Preface

The following high-level summaries for Part 3 buildings are designed to isolate and highlight some potential financial and technical implications of a tiered carbon pollution standard for buildings in British Columbia which local governments may opt-in to.

This document is meant to be an initial costing analysis by illustrating whether decarbonizing a hypothetical building is cost effective across climate zones in B.C.

This document should not be considered an exhaustive costing study to meet the carbon pollution steps in your area. This analysis is not representative of all buildings in all situations.

Local governments and the construction industry should conduct more detailed or specific costing analysis which builds on this initial analysis.

The analysis prioritizes the most commonly built archetypes and scenarios; therefore, not all Steps were analyzed for all climate zones. Excel files with analysis from the Metrics Research Report update will be made available once the report and analysis are complete so stakeholders may conduct their own analysis.

Document format

The following pages contain:

- A proposed table of GHGI targets that could be inserted into the BC Building Code
- An example of how several buildings would meet the carbon pollution Steps

Authors and sources

The report was written by the Building and Safety Standards Branch of the Province of British Columbia, using data and analysis from the 2021 update to the BC Energy Step Code Metrics Research Report, written by Evoke Buildings and E3 Eco Group. More examples may be found in the Metrics Research Report. Thanks to Alex Blue, Einar Halbig, Donald Fast, and M'Beth Schoenfeld.

Assumptions

- *Electricity emissions factor: 0.011kg CO2e/kWh as listed currently in the BC Building Code*
- *Natural Gas emissions factor: 0.185kg CO2e/kWh as listed currently in the BC Building Code*
- *Renewable gas emissions factor: 0.001kg CO2e/kWh (converted from 0.29kg CO2e/GJ as described in the BC Best Practices Methodology for Quantifying Greenhouse Gas Emissions and rounded to the nearest thousandth)*
- *Cost of 100% conventional natural gas: $0.042 $/kWh*
- *Cost of 100% RNG blend: $0.066 $/kWh*
- *Cost of BC Hydro residential electricity: $0.094 $/kWh (Step 1) or $0.141 $/kWh (Step 2)*
- *Cost of BC Hydro commercial electricity: $0.068 $/kWh + 12.4 $/kW*
- *Carbon tax rate: $45 in 2021, $50 in 2022, Linear increase to $170 in 2030 Escalate to $300 at final year of 20 year period (linear increase $13/year)*
- *Annual utility costs consider an annual average rate over 20 years, including a 2% per year utility escalation rate and a 3% discount rate.*

Other assumptions:

- *Other costing data, such as panel size or service upgrade charges, are not included in this analysis given the unique nature of those costs to each project.*
- *Electric vehicle (EV) charging is not included in energy models.*
- *Cooling was included in all Part 3 models; MURBs may not be designed with this in all cases, however the operating GHG impact is very small.*
- *Heat pump domestic hot water heaters were not modeled in this study; these are likely to be a common and viable decarbonisation measure but were excluded to reduce modelling runs.*
- *All values throughout this document, as well as potential GHGI targets and compliance paths, use modeled values, which may differ from eventual metered results.*
- *Equipment efficiencies:*
    - *DHW: electric tank (0.82 EF), natural gas tank (0.67 EF), natural gas tankless (0.95 EF), ASHP integrated tank (1.90 EF)*
    - *Space Heating: natural gas furnace (95% AFUE), electric baseboard, Cold Climate ASHP for CZs 6-8 (COPs from NRCan calculator based on NEEP data) with back up heat same as base case if needed, regular heat pump for CZs 4 and 5 (HSPF 7.1/SEER 14.5) with back up heat same as base case if needed*
- *Financial incentives were not included in this analysis as they change frequently*

Last revised: September 28, 2022

Approach

Three levels of target

The GHG Targets are set as follows:

- Medium: intended to require decarbonization of one major system (space heating or hot water).
- Low: intended to require both major systems to decarbonize, but still allows for high-carbon fuel backup heating, cooking loads, or similar.
- Zero-Carbon Ready: All energy end-uses on a low-carbon fuel.

Intensity targets (GHGI)

The targets are set using an intensity metric, similar to the existing TEUI and TEDI Step Code metrics, which scale by floor area.

Reasoning

Three levels of target

- Each GHG target is set at a level which drives a technology or design choice towards lower carbon fuels.

Intensity targets (GHGI)

- Part 3 buildings vary widely in size, and their energy use generally tracks with size (i.e. there is not a substantial portion of fixed loads that stay the same regardless of size).

Proposed Targets

(all GHGI targets in $kgCO_2e/m^2/year$)	Medium	Low	Zero Carbon Ready
MURB	7	3	1.8
Office	5	3	1.5
Retail	6	3	2
Hotel	9	4	2

Rationale for Targets

Initial discussion on targets centred around a 6/3/1 set of targets. This format is generally adhered to, however some changes for individual archetypes have been suggested above to better target the desired level of decarbonization measures, while remaining achievable without requiring renewables such as solar photovoltaics.

Maximum TEUI/TEDI by Step

First, targets are analyzed based on a simple spreadsheet calculation using the existing Step Code TEUI and TEDI targets, combined with domestic hot water usage modeled in the archetype models. Using these existing targets, and assigning heating and DHW to a high-carbon fuel as an initial baseline (and assuming a 95% condensing boiler for heating), and assuming the rest of the energy use allowable in the TEUI uses a low-carbon fuel given connection to the electrical grid, the following GHGI values (in kgCO2e/m2/year) are seen. This could be considered a “typical worst case” as it uses the maximum allowable TEUI and TEDI for each Step; many projects would be expected to be below those maximums in reality.

The initial targets are set using an allowance based on these maximums, then validated against archetype modelling, described below.

This analysis is summarized below, with levels that would be achieved with each decarbonization measure shown shaded in green.

Target levels

- Each Step and climate zone shows an option to use decarbonization to meet proposed targets at the appropriate decarbonization measures and Steps. In general targets appear to generate the desired outcomes.

- Ability to meet targets does not appear to depend substantially on climate zone but rather on employing effective use of low-carbon fuels. As such and for simplicity, we have proposed a single set of targets for all climate zones.
- Buildings which fully decarbonize would meet the currently proposed zero carbon ready targets. None would meet the initially proposed target of 1 $kgCO_2e/m^2$/year; significant TEUI savings (up to 50% below Step 2 and nearly 40% below Step 4), or use of renewable energy generation such as PV or wind power would be required if a target of 1 was set. This generally holds true in archetype modelling though the office archetype does show some high-efficiency options that would meet a GHGI of 1. All other archetypes do not.
- Office archetype modelling showed several instances of designs with high-carbon backup heating falling into the zero carbon ready targets, and was therefore reduced to 1.5 rather than matching other archetypes. Other archetypes may show similar outcomes in some cases but may have difficulty meeting 1.5 in colder climate zones and have been left as-is.

Impact of Steps

- This analysis also shows the generalized impact of increasing the Step on decarbonization.
- Targeted decarbonization measures have significantly greater impact on GHG savings, compared with much smaller impact from TEUI/TEDI Steps. When increasing Steps without employing targeted decarbonization measures, the carbon savings range from 12% - 30%. The use of decarbonization measures within the same energy Step is in the range of 76% - 92%.
- While moving to a higher energy Step for a particular project may assist in meeting thresholds where they are close, it is not expected to typically be the major driving factor of decarbonization measures selected or the number of decarbonization measures required.

Renewable Natural Gas Analysis

Using renewable natural gas (RG or RNG) can lower the carbon emissions of a building compared to conventional natural gas. This document includes an analysis illustrating the potential blend of renewable gas (RG or RNG) required to achieve the same stepped GHGI targets if all-gas equipment were used.

The use of RNG to meet the GHGI thresholds would only be available if the RNG were purchased in such a way that the building would permanently use low-carbon fuels regardless of change in owner or ratepayer. The annual modelled utility cost of RNG assumes an unlimited supply and is based on rates accurate at the time of writing.

The archetype examples below focus primarily on electrification decarbonization measures; the energy and cost implications for these measures are more complex and require significant analysis to understand.

Renewable natural gas (RNG) decarbonization measures are much simpler from an analysis perspective:

- Use of RNG does not require changes to natural gas baseline equipment and therefore do not incur incremental capital costs.
- Utility cost of RNG in the analysis ends up cost neutral with natural gas once escalating carbon taxes over a 20-year period are accounted for (see assumptions above for more detail.)
- Thus, RNG becomes a simple 1:1 substitution for the modeled base case, which is typically natural gas.
- The main issue considered is therefore what blend of RNG, as a percentage of total natural gas, would be sufficient to meet GHG targets? This is shown below.

The percentage of RNG required to meet targets is shown as a range because it will typically depend on the climate zone, with warmer climate zones requiring a lower percentage and colder climate zones requiring a higher percentage. The percentage required will vary with project specifics and design, for example a design that reduces natural gas heating loads would require a lower percentage of RNG. The below should be considered as a non-exhaustive example only. The below uses Step 2 as a base case.

Archetype	**% RNG to meet Medium GHG Target**	**% RNG to meet Low GHG Target**	**% RNG to meet Zero-Carbon Ready GHG Target**
MURB (high and low rise)	50% - 70%	75% - 85%	90% – 95%
Office	50%	75%	95%
Retail	30% - 60%	75% - 85%	90% – 95%
Hotel	60%	85% - 90%	95% - 97%

Examples of Archetypes

The tables below contain examples of modeled greenhouse gas emissions for a particular archetype, location, and set of design measures. The “base case” within the table uses a high-carbon fuel and approximately Step 2 design measures (envelope, heat recovery) to set an initial baseline prior to decarbonization. Decarbonization measures are then applied to heating and domestic hot water, separately and in combination. This is not an exhaustive list of options to meet targets but is meant to demonstrate a few example points, with key metrics including incremental capital cost, utility cost, and the GHG target level achieved.

Targets Achieved

- Each archetype shows at least one fully decarbonized, zero carbon ready option.
- Designs using one decarbonization measure generally meet medium targets, as expected. In some cases a particular measure (either heating or DHW) must be used.
- Designs using high-carbon backup heating fuel generally achieve the Low target, as expected. There are some cases where they meet either Medium or Zero Carbon ready; these targets fall into a narrow range with some overlap.

Cost Impacts

- Costs for decarbonization remain within 2.5% for all archetypes modelled, to reach Zero Carbon Ready.
- The cost difference between decarbonization measures for Climate Zone 7a versus 4 is consistently between 0.2% - 0.3% across all archetypes considered. This is further discussed below but suggests a bookending approach to Part 3 decarbonization cost considerations and modelling is appropriate.

Mixed Use Buildings

Mixed use buildings have not been modeled within these data sheets; it is anticipated that they would follow the procedure outlined in the City of Vancouver Energy Modelling Guidelines

Impact of Steps

A Step 2 base case as well as the impacts of higher Steps are shown for all archetypes. Key observations from this analysis are summarized here.

- Achieving a higher Step will reduce annual heating loads (TEDI) as well as overall energy (TEUI). This leads to carbon reductions, particularly if the heating is supplied by a high-carbon fuel.
- However, efficiency improvements are not a substitute for targeted decarbonization measures. While projects are likely to employ both in combination to some extent, decarbonization measures and targets require over 30% reductions in carbon between levels, and in many cases greater reductions from typical design to even the Medium target. 30% or greater reduction in energy use beyond Step 2 is significant and would require substantial design interventions (this would mean reducing EUI from Step 2 to somewhat below Step 4 for a MURB.) On the other hand, employing the use of targeted decarbonization measures including RNG and electrification can readily achieve those levels.
- As such, the below archetype analysis focusses on targeted decarbonization measures, including RNG and electrification measures.
- However, significant impacts for a design employing a higher Step would include:
    - Reduced operating costs (via a reduction in load).
    - Potential for reduced equipment size

Last revised: September 28, 2022

The below table provides the average incremental capital cost (ICC), for the 10 lowest ICC options for each archetype, Step, and climate zone, prior to applying any decarbonization measures. This can be considered along with the decarbonization costs in the data tables below.

	Lowest ICC Options for each Step prior to Decarbonization

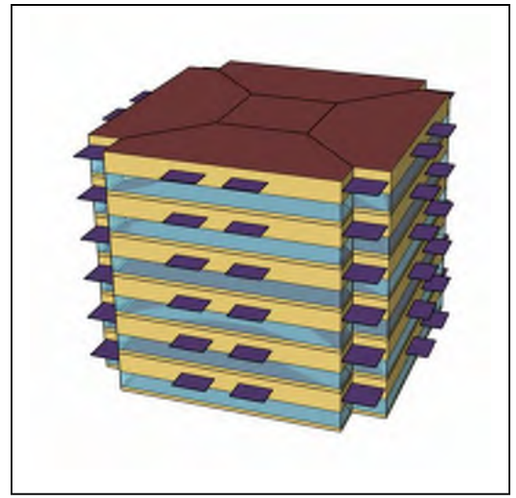
Last revised: September 28, 2022

Low-rise multi-unit residential building (MURB) Archetype

Base case

- 100% conventional natural gas (to isolate changes and costs related to carbon requirements)
- Vertical surface area to floor area ratio (VFAR): 0.6
- Medium density (approx. 55m^2 average unit size)
- Cooling equipment: Packaged terminal air conditioner (PTAC) units in suites, or fan coils if heating system is FC.



In some cases, energy costs shown for ASHP cases are higher than those shown for electric baseboard cases. Savings are expected due to better heating efficiency in the ASHP case. However, the base model for the ASHP case includes conservative (NECB baseline) fan power which increases utility costs for this case. In design scenarios using improved fan designs utility cost savings would be anticipated.

[6] Heat pump water heaters were not included in this analysis because they were not included in the modelling completed for the 2021 Metrics Report Update

Last revised: September 28, 2022

High-rise multi-unit residential building (MURB) Archetype

Base case

- 100% conventional natural gas (to isolate changes and costs related to carbon requirements)
- Vertical surface area to floor area ratio (VFAR): 0.6
- Medium density (approx. 55m^2 average unit size)
- Cooling equipment: Packaged terminal air conditioner (PTAC) units in suites, or fan coils if heating system is FC

In some cases, energy costs shown for ASHP cases are higher than those shown for electric baseboard cases. Savings are expected due to better heating efficiency in the ASHP case. However, the base model for the ASHP case includes conservative (NECB baseline) fan power which increases utility costs for this case. In design scenarios using improved fan designs utility cost savings would be anticipated.

Highlights from analysis

- DHW is fairly low for this archetype; larger focus on space heating.
- DHW heat pumps were not modeled but could be used; GHGI outcomes would typically be similar to electric resistance DHW heating, though the addition of a DHW heat pump in a conditioned space can increase heating loads and may impact overall GHGI depending on space heating fuel source. Project-specific modelling should be used to confirm impacts.

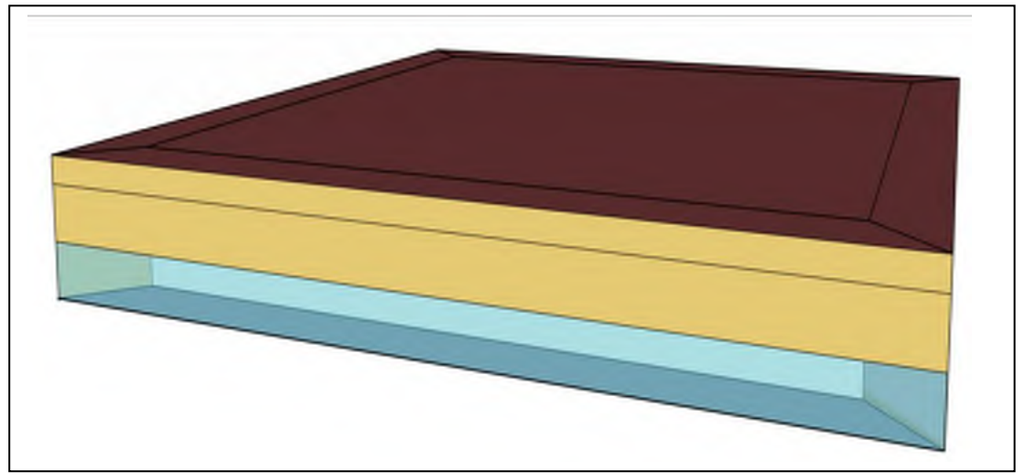
Retail Archetype



Base case

- 100% conventional natural gas (to isolate changes and costs related to carbon requirements)
- 25% lighting savings vs NECB 2015
- Looking at Mall results rather than big box, as mall has higher GHGI.

Step	ECM	Climate Zone 4	Climate Zone 5	Climate Zone 6	Climate Zone 7a
Base Case: Step 2	Walls	R-10	R-20	R-20	R-20
	Roof	R-40	R-60	R-60	R-40
	WWR	20%	20%	20%	20%
	Windows	USI 2.0	USI 1.2	USI 1.2	USI 1.6
	SHGC	0.3	0.3	0.3	0.3
	Infiltration	No savings beyond code	No savings beyond code	50% savings vs code	50% savings vs code
	HRV	60%	60%	60%	80%
Step 3	Walls	R-20	R-20	R-20	R-40
	Roof	R-60	R-60	R-60	R-60
	WWR	20%	20%	20%	20%
	Windows	USI 2.0	USI 2.0	USI 2.0	USI 0.8
	SHGC	0.3	0.3	0.3	0.3
	Infiltration	50% savings vs code	No savings beyond code	50% savings vs code	50% savings vs code
	HRV	60%	80%	80%	80%

Highlights from analysis

- GHGIs depend on space mix/archetype.
    - GHGIs are higher in malls than in big box stores (used malls in the table, difference on base case fully natural gas is approx. 1.7 GHGI; difference becomes negligible in lowest GHG cases)
- DHW is relatively low for this archetype; larger focus on space heating.
- DHW heat pumps were not modeled but could be used; GHGI outcomes would typically be similar to electric resistance DHW heating, though the addition of a DHW heat pump in a conditioned space can increase heating loads and may impact overall GHGI depending on space heating fuel source. Project-specific modelling should be used to confirm impacts.

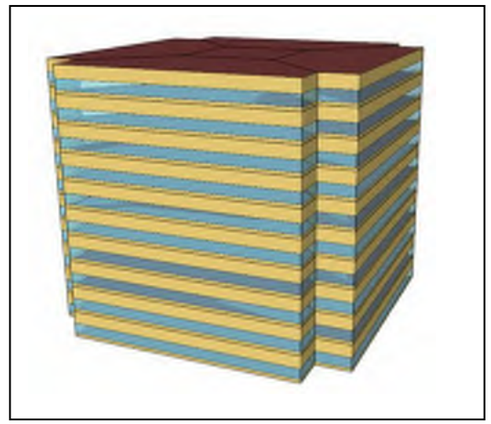
[xviii] Heat pump water heaters were not included in this analysis because they were not included in the modelling completed for the 2021 Metrics Report Update

Hotel Archetype



Base case

- 100% conventional natural gas (to isolate changes and costs related to carbon requirements)
- 20% lighting savings
- Pool heating fuel source matches the building heating fuel source
- Systems are 4-pipe fan coils with dedicated outdoor air system (DOAS)

Highlights from analysis

- There is higher laundry use in these archetypes (10%+ of energy use), so laundry energy source affects GHGI.
- DHW heat pumps were not modeled but could be used; GHGI outcomes would typically be similar to electric resistance DHW heating, though the addition of a DHW heat pump in a conditioned space can increase heating loads and may impact overall GHGI depending on space heating fuel source. Project-specific modelling should be used to confirm impacts.

Preface

The following data tables for Part 9 buildings are designed to isolate and highlight some potential financial and technical implications of a tiered carbon pollution standard for buildings in British Columbia which local governments may opt-in to.

This document is meant to be an initial costing analysis by illustrating whether decarbonizing a hypothetical building is cost effective across climate zones in B.C.

This document should not be considered an exhaustive costing study to meet the carbon pollution steps in your area. This analysis is not representative of all buildings in all situations.

Local governments and the construction industry should conduct more detailed or specific costing analysis which builds on this initial analysis.

Not all Steps and archetypes were analyzed for all climate zones. Excel files with analysis from the Metrics Research Report update will be made available once the report and analysis are complete so interested parties may conduct their own analysis.

Document format

The following pages contain:

- A proposed table of GHGI/GHG targets that could be inserted into the BC Building Code
- An example of how several building would meet the carbon pollution Steps

Authors and sources

The report was written by the Building and Safety Standards Branch of the Province of British Columbia, using data and analysis from the 2021 update to the BC Energy Step Code Metrics Research Report, written by Evoke Buildings and E3 Eco Group. More examples may be found in the Metrics Research Report. Thanks to Alex Blue, Einar Halbig, Donald Fast, and M'Beth Schoenfeld.

Assumptions

- *Electricity emissions factor: 0.011kg CO2e/kWh as listed currently in the BC Building Code*
- *Natural Gas emissions factor: 0.185kg CO2e/kWh as listed currently in the BC Building Code*
- *Renewable gas emissions factor: 0.001kg CO2e/kWh (converted from 0.29kg CO2e/GJ as described in the BC Best Practices Methodology for Quantifying Greenhouse Gas Emissions and rounded to the nearest thousandth)*
- *Cost of 100% conventional natural gas: $0.042 $/kWh*
- *Cost of 100% RNG blend: $0.066 $/kWh*
- *Cost of BC Hydro residential electricity: $0.094 $/kWh (Step 1) or $0.141 $/kWh (Step 2)*
- *Cost of BC Hydro commercial electricity: $0.068 $/kWh + 12.4 $/kW*
- *Carbon tax rate: $45 in 2021, $50 in 2022, Linear increase to $170 in 2030 Escalate to $300 at final year of 20 year period (linear increase $13/year)*

Other assumptions:

- *Other costing data, such as panel size or service upgrade charges, are not included in this analysis given the unique nature of those costs to each project.*
- *Electric vehicle (EV) charging is not included in energy models.*
- *All values throughout this document, as well as potential GHGI targets and compliance paths, use modeled values, which may differ from eventual metered results.*
- *Equipment efficiencies:*
    - *DHW: electric tank (0.82 EF), natural gas tank (0.67 EF), natural gas tankless (0.95 EF), ASHP integrated tank (1.90 EF)*
    - *Space Heating: natural gas furnace (95% AFUE), electric baseboard, Cold Climate ASHP for CZs 6-8 (COPs from NRCan calculator based on NEEP data) with back up heat same as base case if needed, regular heat pump for CZs 4 and 5 (HSPF 7.1/SEER 14.5) with back up heat same as base case if needed*
- *Financial incentives were not included in this analysis as they change frequently*

Approach

Three levels of target

The GHG Targets are set as follows:

- Medium: The larger of either heating or DHW must use a low-carbon fuel.
- Low: Allows for smaller end uses such as cooking or gas dryers to use high-carbon fuel, or allows use of a small portion of high carbon fuel for large end uses (e.g. backup heating) but requires low-carbon fuel for most end-uses.
- Zero-Carbon Ready: All energy end-uses on a low-carbon fuel.

Building Size

Building size is accounted for by setting an absolute base allowance and a maximum cap per unit for all buildings, then scaling the GHG targets linearly by size of dwelling between the base allowance and maximum cap for each level. The unit base allowance was set for 200 m^2 dwelling unit, the maximum cap based on a 400 m^2 dwelling unit.

The targets would be scaled by number of dwelling units in the building; e.g. a 4-plex would have four times the base per-unit allowance.

Climate Zone

All Climate Zones use the same targets without scaling.

Prescriptive Option

A potential prescriptive option is considered to act as a backstop target for compliance, but is less flexible.

Modelling Guidelines Required

Modelling guidelines may be required to ensure alignment between projects, including:

- GHG emission factors.
- Modelling auxiliary loads such as cooking loads, fireplaces, dryers, etc. using the appropriate fuels.
- Modelling backup heating appropriately.
- Modelling or excluding exterior loads such as pools, fireplaces, or BBQs.

Reasoning

Target levels

- Each GHG Step is set at a level which drives a technology or design choice towards lower carbon fuels.
- Targets are set using current Step 3 MEUI and TEDI targets, as well as an additional allowance for plug loads, lighting, and other base electric loads.
    - This means each GHGI target is designed to be realistic for a Step 3 home to achieve when it decarbonizes one or more systems such as domestic hot water or heating.
    - This also means that each GHGI target should, in theory, be even easier to achieve if a home meets Steps 4 or 5.

Building Size

- The base allowance per unit allows for fixed loads, such as domestic hot water or plug loads, that do not depend on the size of the dwelling. Assists modelling, design and construction of small, affordable housing units, while having minimal GHG impacts.
- The maximum cap per unit reflects that it is easier to achieve GHGI reductions in larger buildings.
- The GHGI variation between the minimum and maximum targets is used to drive efficient low-carbon building and mechanical design.

Climate Zone

- Using the same targets for all climates reduces complexity.
- Targets appear to be achievable in all Climate Zones for all archetypes.
- The use of fuel switching causes significant reductions regardless of loads. Break points remain between the target levels that generally encourage decarbonization at the appropriate levels.

- However, this can make more stringent targets in colder climate zones more challenging and introduce cost differentials.

Prescriptive option

- The prescriptive target levels are aligned with the intent of how each modeled target was set. The Medium target proposes to require heating to be decarbonized regardless of whether heating or domestic hot water would be more impactful for a particular building. Heating would be more impactful for buildings with higher absolute GHG use, in particular larger homes as well as those in colder climates. Therefore, for the backstop prescriptive target, the larger total impact measure across all dwellings is proposed as the requirement.

Proposed Targets

	All Buildings:		**The smaller of GHG intensity or the maximum absolute cap, for the unit size.**			**Prescriptive option (under consideration)**
	GHG Base Allowance per unit		**Building GHG Intensity**	**GHG Maximum Cap per unit**		
	kg CO2e per unit	OR	kgCO2e/m2/year	kg CO2e per unit	OR	
Medium	1050		6	2400		Decarbonize heating.
Low	440		2.5	800		Only backup heating or auxiliary uses (cooking, fireplaces, etc.) are allowed to use high carbon fuel.
Zero Carbon Ready	265		1.5	500		Project is fully decarbonized.

Last revised: September 28, 2022

Renewable Natural Gas Analysis

Using renewable natural gas (RG or RNG) can lower the carbon emissions of a building compared to conventional natural gas. This document includes an analysis illustrating the potential blend of renewable gas (RG or RNG) required to achieve the same stepped GHGI targets if all-gas equipment were used.

The use of RNG to meet the GHGI thresholds would only be available if the RNG were purchased in such a way that the building would permanently use low-carbon fuels regardless of change in owner or ratepayer. The annual modelled utility cost of RNG assumes an unlimited supply and is based on rates accurate at the time of writing.

The archetype examples focus primarily on electrification decarbonization measures because the energy and cost implications for these measures are more complex and require significant analysis to understand.

Renewable natural gas (RNG) decarbonization measures are much simpler from an analysis perspective:

- Use of RNG does not require changes to natural gas baseline equipment and therefore do not incur incremental capital costs.
- Utility cost of RNG in our analysis ends up cost neutral with natural gas once escalating carbon taxes over a 20-year period are accounted for (see assumptions above for more detail.)
- Thus, RNG becomes a simple 1:1 substitution for the modeled base case, which is typically natural gas.
- Therefore, what blend of RNG, as a percentage of total natural gas, would be sufficient to meet GHG targets?

The percentage of RNG required to meet targets is shown as a range because it will depend on the size of the dwelling (50 m^2 to 225 m^2 is shown below), with smaller homes requiring less RNG to meet targets. The percentage required will also vary with project specifics and design, for example a design that reduces natural gas heating loads would require a lower percentage of RNG. the below should be considered as a non-exhaustive example only. The below uses Step 3 as a base case.

Climate Zone	% RNG to meet Medium GHG Target	% RNG to meet Low GHG Target	% RNG to meet Zero Carbon Ready GHG Target
4	15% - 50%	70% - 80%	85% - 90%
5	20% - 80%	60% - 90%	70% - 90%
6	30% - 80%	65% - 90%	75% - 95%
7a	35% - 70%	75% - 90%	90% - 95%
7b	45% - 75%	80% - 90%	90% - 95%
8	50% - 80%	80% - 90%	90% - 95%

Example of archetypes

The tables below contain examples of modeled greenhouse gas emissions for a particular archetype, location, and set of design measures. The “base case” within the table uses a high-carbon fuel and varied initial Step level design measures (envelope, heat recovery) to set an initial baseline prior to decarbonization. Decarbonization measures are then applied to heating and domestic hot water, separately and in combination. This is not an exhaustive list of options to meet targets but is meant to demonstrate a few example points, with key metrics including incremental capital cost, utility cost, and the GHG target level achieved. It should be noted that drainwater heat recovery has been excluded from all options for consistency and comparability of results between different Steps but could certainly be applied on projects to reduce domestic hot water load and associated GHGs. In some cases, slightly different measures are provided at different Step levels due to available modelling runs from the Metrics Research Report modelling done.

Levels achieved are determined based on the allowance, GHGI, and maximum cap. Prescriptive compliance paths have yet to be fully developed and are not noted.

Some key points:

Targets Achieved

- Each archetype in each Climate Zone shows at least one fully decarbonized, Zero Carbon Ready option.
- Each archetype shows at least one mid-range option, which will typically comply with the Medium target.
- Not all decarbonization measures have the same impact for each archetype and Climate Zone. Decarbonizing only the smaller of the two end uses may not be sufficient. In many cases the higher impact of space heating or hot water will need to be decarbonized to meet targets.
- Most archetypes below achieve either no target, Medium, or Zero Carbon Ready. Only a few achieve the Low target. This is because the Low target is set to still require major systems to be decarbonized, but to allow some buffer for smaller end uses such as cooking, gas dryers, or some amount of backup heating. The archetypes modeled use electricity for these end uses by default and use cold climate heat pumps in Climate Zones 6 and above.

Carbon reduction impacts

A few examples of the amount of carbon reduction are below:

- Laneway home in Vancouver: **89% reduction** from Step 3 base case to Step 3 fully decarbonized.
- Large single family dwelling in Summerland: **95% reduction** from Step 3 base case to Step 3 fully decarbonized.
- Quadplex in Fort St. John: **93% reduction** from Step 3 base case to Step 3 fully decarbonized.
- Medium single family dwelling in Cranbrook: **70% reduction** from Step 3 base case to Step 3 Middle target.
- 10-unit MURB in Fort Nelson: **76% reduction** from Step 3 base case to Step 3 Middle target.

Cost Impacts

- Maximum incremental capital cost for any of the below examples in all Climate Zones, including zero-carbon ready targets, is 3.4%. Typical incremental capital cost for most archetypes is lower, generally below 1.5%.
- Utility costs typically range from approximately 30% savings to 30% increase in costs related to decarbonization. Climate Zones 7b and 8 show larger increases, ranging up to 60%. There is not a linear relationship between decarbonization and utility costs; with efficiency improvements as well as increasing carbon taxes there are a range of utility cost outcomes shown.
- Utility cost impacts tend to show:
    - Greatest increase when employing electric resistance space heating (which is less efficient than a heat pump)
    - Greatest decrease when using heat pumps for both space heating and hot water

Electric Resistance Heating

In general, heat pumps are used as a decarbonization measure for both heating and domestic hot water. There are a few examples that demonstrate the difference between electric resistance systems (such as electric baseboard) and heat pump for space heating. While these are somewhat less efficient, they generally can be applied as a decarbonization measure. They would typically have lower incremental cost and higher energy cost, and similar but slightly poorer GHG outcomes. The difference in GHG outcomes is likely to be negligible to most projects and electric resistance could be applied; in particular cases where a design is right at the edge of a target it may not be useable. The same principles apply to using electric resistance for DHW.

Low Target and Backup Heating

The “low” target is intended to allow for some backup or auxiliary high-carbon fuel use but for all major systems to be decarbonized. The modelling done for the Metrics Research Report Update used the low-carbon default fuels for auxiliary uses such as cooking, dryers, etc. Heat pumps modeled for the archetype buildings are cold climate air source heat pumps in Climate Zones 6 and above, and use electric resistance backup/supplemental heating where required.

The amount of backup high-carbon fuel allowed for (with the rest of the building fully decarbonized) is equivalent to approximately:

- For a large single family dwelling in Fort St. John (Climate Zone 7a)
    - 12% of Step 3 total annual heating load
    - 15% of Step 5 total annual heating load
- For a quadplex in Fort St. John (Climate Zone 7a)
    - 30% of a Step 4 total annual heating load
- For a large single family dwelling in Uranium City (Climate Zone 8)
    - Only allows for 3% of Step 3 total annual heating load.
    - These projects would likely use the prescriptive option to meet targets. Compliance is also possible if the project fully decarbonizes and does not use high-carbon backup fuel.
