Executive Summary

The BC Energy Step Code is currently an optional compliance path in the BC Building Code (BCBC) that local governments may use, if they wish, to incentivize or require a level of energy efficiency in new construction where higher Steps go above and beyond the requirements of the base BC Building Code. Projects may voluntarily use the BC Energy Step Code as a compliance path for meeting the energy efficiency requirements of the BC Building Code.

In keeping with the federal government's Build Smart: Canada's Buildings Strategy, the Province has committed to having a net-zero energy ready standard for new construction by 2032. This change will be enacted step by step through the BC Building Code. Compared to the 2018 base BC Building Code, new homes and buildings will be:

20% more energy efficient by 2022

40% more energy efficient by 2027

80% more energy efficient by 2032 – the net zero energy ready standard

This study updates and expands on previous work completed in the 2017 and 2018 Metrics Research Reports, with a focus on updating analysis that will determine appropriate energy efficiency requirements to include in BCBC 2022 given the CleanBC commitment to shift to a new baseline that is approximately 20% better than BCBC 2018, as well as providing a consistent set of greenhouse gas emission related targets. The study also conducts an overheating risk analysis using current and future typical weather data.

Archetype energy modelling is used for a number of Part 9 and Part 3 building types.

For Part 3 buildings, a shift to Step 2 as the minimum Step for all modeled archetypes is recommended; this generally fulfills both the need for the new baseline to meet NECB 2020 as well as to be approximately 20% better than BCBC 2018.

Overheating risk analysis is conducted for Part 3 multi-unit residential buildings, and identifies a number of passive cooling measures that can be combined to achieve targets of under 200 hours overheated, aligned with the City of Vancouver Energy Modelling Guidelines v2 targets, with the exception of the climate zone 5 location modeled (Kamloops) which is not able to meet this target based on the modelling conducted due to hotter typical summer weather. The analysis identifies challenges with meeting a 20-hour target for vulnerable populations even in 2020's projected weather files, with only climate zone 4 able to meet this target based on the measures modeled. In addition, future-projected 2050s weather was analyzed and shows considerable warming and increased overheated hours.

The overheating risk analysis also notes significant limitations with passive cooling measures in extreme weather events including life safety issues such as those seen in the heat dome in 2021. These events are not accounted for in even future-projected energy modelling weather files. Both passive and active cooling measures should be considered in combination to reduce risk and improve resilience.

Greenhouse gas emission targets are proposed for both Part 9 and Part 3 buildings. In both cases, three levels are proposed, with “medium” targets intended to require one significant decarbonization measure, “low” targets to require decarbonization of all major systems but allowing for some backup heating or auxiliary uses such as cooking, and “zero carbon ready” to require full decarbonization.

For Part 9 buildings, analysis of the new laneway home archetype shows that to achieve the same Step level as larger homes, additional energy conservation measures are required, and these represent a larger percentage of the overall project cost.

Analysis of variations of window to wall ratio as well as surface area ratio for the medium and large single family dwelling show that both can have a significant energy impact and require additional energy conservation measures (and associated costs) to maintain performance. Both are typically design choices, where the increased energy use can be compensated for with other design measures. However a minimum level of articulation, for example, may be required by some jurisdictions. Jurisdictions adopting the BC Energy Step Code should consider their other policies for alignment with Step Code goals.

List of Abbreviations

ACH: Air changes per hour

AFUE: Annual fuel utilization efficiency

ASHP / CCASHP : Air-source heat pump / cold-climate air-source heat pump

BCBC: British Columbia Building Code

Cfm: Cubic feet per minute

COP: Coefficient of performance

CoV EMGv2: City of Vancouver Energy Modelling Guidelines version 2

CZ: Climate zone

DHW: Domestic hot water

DOAS: Dedicated outdoor air system

ECM: Energy conservation measure

Elec: Electricity

ERS: EnerGuide Rating System

FC: Fan coil

GHG / GHGI: Greenhouse gas emissions / greenhouse gas emissions intensity

HP: Heat pump

HRV / ERV: Heat recovery ventilator / energy recovery ventilator

HSPF: Heating seasonal performance factor for heat pumps

HTAP: Housing Technology Assessment Platform

HVAC: Heating, ventilation, and air conditioning

ICC: Incremental capital cost

LEEP: Local Energy Efficiency Partnerships

LPD: Lighting power density

MEUI: Mechanical energy use intensity

MURB: Multi-unit residential building

NECB: National Energy Code for Buildings

NG / RNG: Natural gas / renewable natural gas

NPV: Net present value

PV: Photovoltaic

RTU: Rooftop unit

SHGC: Solar heat gain coefficient

TEDI: Thermal energy demand intensity

TEUI: Total energy use intensity

VAV: Variable air volume (as a mechanical system)

VRF: Variable refrigerant flow

WWR: Window to wall ratio

1 Introduction

The BC Energy Step Code is currently an optional compliance path in the BC Building Code (BCBC) that local governments may use, if they wish, to incentivize or require a level of energy efficiency in new construction where higher Steps go above and beyond the requirements of the base BC Building Code. Projects may voluntarily use the BC Energy Step Code as a compliance path for meeting the energy efficiency requirements of the BC Building Code.

In keeping with the federal government's Build Smart: Canada's Buildings Strategy and the Pan-Canadian Framework on Clean Growth and Climate Change, the Province has committed to having a net-zero energy ready standard for new construction by 2032. This change will be enacted step by step through the BC Building Code. Compared to the 2018 base BC Building Code, new homes and buildings will be:

20% more energy efficient by 2022

40% more energy efficient by 2027

80% more energy efficient by 2032 – the net zero energy ready standard

This study updates and expands on previous work completed in the 2017 and 2018 Metrics Research Reports, with a focus on updating analysis that will determine appropriate energy efficiency requirements to include in BCBC 2022 given the CleanBC commitment to shift to a new baseline that is approximately 20% better than BCBC 2018, as well as providing a consistent set of greenhouse gas emission related targets to be applied by local governments. The study also conducts an overheating risk analysis using current and future typical weather data.

The study uses energy modelling and cost data to examine the costs associated with achieving the proposed metrics, and to obtain optimized costing results for two primary metrics: incremental capital costs, net present value (NPV) as well as a focus on carbon abatement costs. The study also examines the potential impacts of greenhouse gas emissions targets and conducts an overheating risk analysis.

In addition, analysis has been expanded to add a smaller/laneway house for Part 9, and to add analysis on window to wall ratio and form factor for Part 9.

The current targets of the BC Energy Step Code are available in Sections 9.36.6 and 10.2 of the 2018 BC Building Code, available online via https://bccodes.ca/index.html.

1.1 Team

All analysis was conducted by Evoke Buildings Engineering and E3 Eco Group.

1.2 Limitations

- The study is limited to the particular archetypes and measures studied.

  - It is not intended as a design guide. The study includes a limited number of scenarios, and it is unlikely any single building design will fully match archetype inputs or results.
  - Variations in size as well as shapes of buildings can have significant impacts and are not considered for all archetypes. Small, narrow, or particularly complex buildings are likely to require different approaches.

- Part 9: surface area ratio and window to wall ratio variations were considered only for medium and large single family dwellings within this study.
- Costing information is high level and is expected to vary by project. Costs exclude incentives.
- The study focusses on new construction only; existing buildings are not considered.
- Upcoming changes to the code may reference ANSI/ASHRAE Standard 62.1-2016: Ventilation for Acceptable Indoor Air Quality, rather than the currently referenced ASHRAE 62.1-2001 without Addendum N. This change would be significant and would impact energy. The proposed new ASHRAE 62.1-2016 ventilation rates are modelled throughout this study. Individual projects would be expected to model ventilation rates as-designed, which may be higher than the code minimum requirement and may require additional energy conservation measures to achieve targets.
- District energy has not been evaluated within this study. There are a large number of possible designs and compliance treatments for district energy and it has been excluded from this analysis.
- Overheating:
  - Overheating is a life safety issue and should be looked at in a broader context to develop adequate regulations.
  - Only Part 3 MURBs have been considered in the overheating analysis. Part 9 modelling software does not have adequate overheating analysis capabilities. Part 3 commercial buildings typically have mechanical cooling measures and would be expected to conduct in-depth analysis of any passive or hybrid cooling measures used.
  - Weather files consider only typical weather years. They do not consider extreme weather events, including heat waves. These are times when passive cooling measures may not function as well due to high outdoor air temperatures or wildfire smoke. Extreme weather events are expected to increase in severity and frequency as climate change continues.
  - Temperature limits are based on ASHRAE 80% Acceptability Limits, although they are simplified compared with the full standard to allow for more straightforward integration with energy modelling software and workflows to provide a first

order analysis. However the use of 80% acceptability limits is itself a limitation of the analysis. Thermal comfort is highly variable depending on individual needs and preferences, and the 80% acceptability limit intends only to satisfy 80% of occupants, potentially leaving 1 in every 5 occupants in uncomfortable conditions even when the standard is met.

        - In addition, the 80% acceptability limits are only applicable for systems where the following conditions are true: (a) There is no mechanical cooling system installed. No heating system is in operation; (b) Metabolic rates ranging from 1.0 to 1.3 met; and (c) Occupants are free to adapt their clothing to the indoor and/or outdoor thermal conditions within a range at least as wide as 0.5-1.0 clo. (Source: CBE Thermal Comfort Tool for ASHRAE-55 (berkeley.edu)). In general this is expected to apply to the MURBs considered in this study; however should be noted as a limitation.

    - Energy modelling software has limitations in relation to overheating risk. EnergyPlus was used in this study, and notably only has a single temperature node within each zone. It does not account for differentials within the zone, or for local discomfort effects.

    - The archetype analysis workflow has limitations in terms of overheating risk analysis. The model uses a single zone per elevation, which may not represent a worst-case scenario for overheating. One possible worst-case may be a very narrow and deep single-façade suite with little opportunity for cross-flow ventilation, or a southwest-facing corner suite with high solar gains. This archetype is used to align with the remainder of the study as well as previous Metrics Report studies. Projects will need to conduct individual analysis specific to their layouts and design strategies.

    - Variations in suite internal loads are not considered within the scope of this study.

    - Radiant temperature is not considered, and dry bulb temperature only is used in the analysis. Some energy modelling programs may be able to consider radiant temperature, however a survey may need to be undertaken to confirm that there is sufficient software capability of considering radiant temperature if doing so were to be required.

- It cannot be said with 100% confidence that all designs meeting Step 2 would meet NECB 2020; this is true of current Step Code targets as well and becomes increasingly true as stringency of the base code increases. This is the nature of comparing absolute and baseline targets. Size and shape of the building are significant energy inputs that are equalized in a baseline model but for which credit or penalty is seen in an absolute target. In addition, certain characteristics of the baseline are dependent on the design,

and may lead to savings against the baseline even while increasing the absolute energy use of the building, or vice-versa.

2 Energy Modelling

An energy modelling analysis has been completed, using archetype buildings developed to represent buildings commonly seen within BC. Both Part 9 (small residential) and Part 3 (large residential and commercial) building types are considered. Cost data has also been gathered from previous studies, local contractors, suppliers, and consultants, and cost databases. Combined with energy model results, this has been used to study incremental capital cost, net present value, and greenhouse gas emissions abatement costs of energy conservation measures examined in the study.

2.1 Part 3 Archetypes

The same building archetypes as used for the original 2017 and 2018 reports were maintained, with changes to models as outlined in this report. The models are developed using EnergyPlus v9.4, and, as was done in 2017 and 2018, the models have been run using a parametric energy modelling tool to simulate a large number of models within a given range of input variations. The parametric runs, for example, can vary the wall R-value, window U-value, and window to wall ratio, one at a time and in combination to see potential impacts. The ECMs and variations simulated are listed in Section 2.1.3.

The archetypes are outlined in the table below. More information is available in Appendix A.

Table 2-1. Archetype descriptions for Part 3

Archetype	Description
High Rise MURB	28-storey high-rise MURB, non-combustible construction Modeled as one zone per façade, with interior core corridor space. Small amenity space, no significant amenity loads (e.g. pools etc).
Low Rise MURB	6-storey wood frame MURB. Same zoning and amenity space as high-rise MURB.
Office	10-storey office building, modeled using core and perimeter zoning.
Retail	Big box and mall options simulated, both single storey with core and perimeter zoning.
Hotel	10-storey hotel including conference areas, pool, and commercial kitchen and laundry, as well as guest suites.

The energy results for the high-rise and low-rise (6-storey) Part 3 MURBs are the same on a per area basis; i.e. they are held to the same standard. However, certain energy conservation measures may be more readily applicable to a low-rise wood framed MURB, such as drainwater heat recovery and higher thermal performance envelope. The costs for measures differ, as we look at wood frame construction for the low-rise MURB and non-combustible construction for the high-rise MURB. Where energy results only are discussed, we roll both discussions together.

2.1.1 NECB 2020

A new edition of the National Energy Code for Buildings, NECB 2020, is forthcoming. With the energy requirements of NECB soon to be updated, this could potentially lead to changes in the BC Building Code, if NECB 2020 becomes the adopted edition of NECB within the BC Building Code. In addition to referencing NECB as Step 1 for applicable Part 3 buildings, the BC Energy Step Code also contains absolute targets for TEUI and TEDI. With a potential update of the BC Building Code to NECB 2020, the absolute TEUI and TEDI targets, or the minimum Step level, may require updates to maintain the relative performance of the higher Steps.

The relevant updates within NECB 2020 are outlined below.

BCBC 2018, which is in force at the time of writing, references NECB 2015. An interim version, NECB 2017, has also been published, and any changes implemented between the currently referenced NECB 2015 and the future NECB 2020, must be modeled. This is discussed further below.

NECB applies to Part 3, though can be applied to Part 9 buildings as well. The Part 9 simulations in this report do not reference NECB.

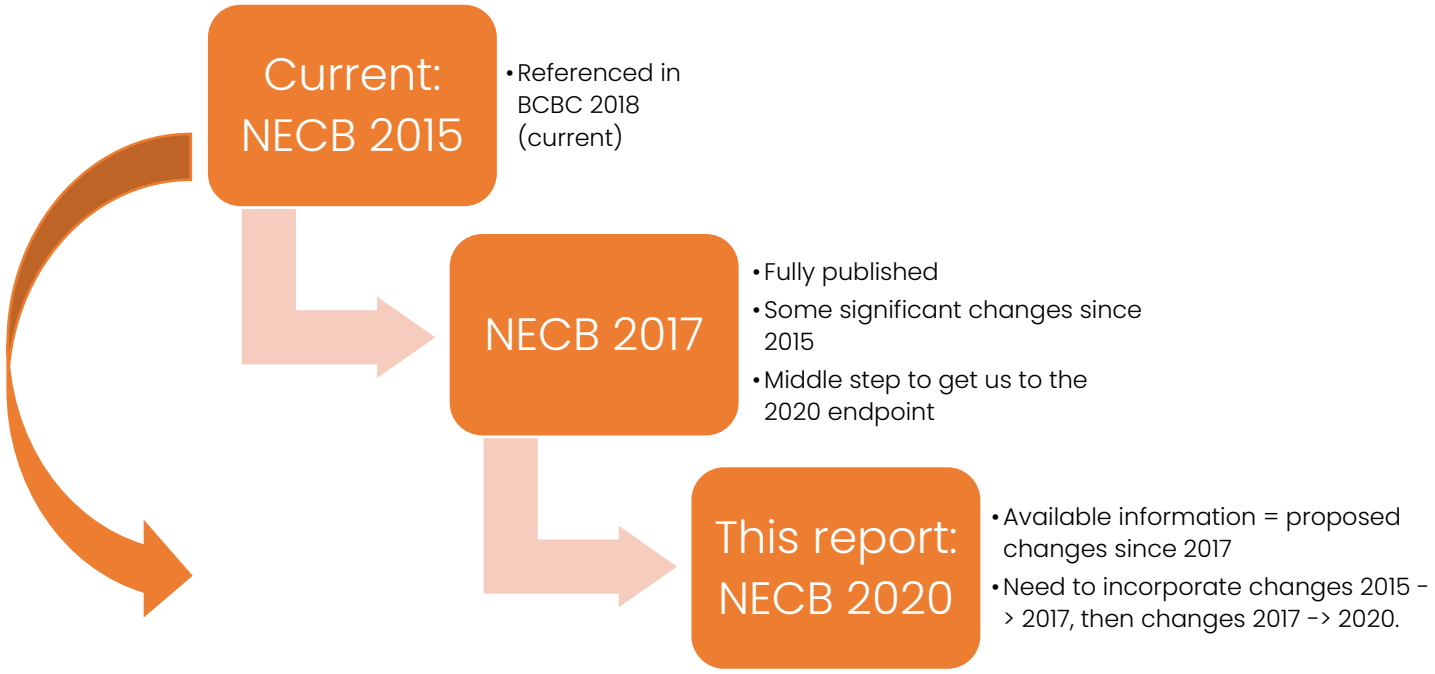
NECB 2020 is not yet published as of the date of this report; as such the modelling is based on the proposed changes, summarized below, as of April 22, 2021.

Table 2-2. Summary of proposed changes in NECB 2020

Proposed Change	Subject	Title	Impact on Modelling Study
1414	Air Leakage	Whole Building Airtightness Testing	None - using CoV modelling guidelines to evaluate airtightness targets, and testing is already required.
1435	Piping and Duct Insulation	Piping Insulation	None - no losses in model; no change to Part 8
1438	Piping and Duct Insulation	Duct and Plenum Insulation	None - no losses in model; no change to Part 8
1456	Interior Lighting Power	Lighting Power Density Improvement - Interior Lighting	Yes - reduced lighting power density per updated tables
1458	Exterior Lighting Power	Treatment of Exterior Applications Currently Not Covered in NECB	None - Exterior lighting allowance only; no savings/particular design modeled.
1460	HVAC Trade-off Path	Deletion of Part 5 and Part 6 Tradeoff Paths	None - following Part 8 (Performance Path)
1527	Performance Compliance - Other	Tiered Energy Performance Compliance	None - Step Code will set its own tiered targets.
1536	Building Envelope - General	Thermal Characteristics of Fenestration and Doors	Yes - improved thermal performance per updated table. Fenestration improvement was approved, doors remain per NECB 2017.
1537	Building Envelope - General	Thermal Characteristics of Opaque Building Assemblies	Yes - improved thermal performance per updated table.

Proposed Change	Subject	Title	Impact on Modelling Study
1549	HVAC - Other	Supply Air Systems	Yes - set zone min airflow for VAV to 30% or OA, and use warmest reset
1621	HVAC Equipment Efficiency Table	HVAC Equipment Performance Requirements	Yes - improved performance per updated table.
1623	Climatic Loads	Update of Wind Pressure Data	No - model sizing based on CWEC 2016 weather files and design days.
1630	Service Water Heating Equipment Efficiency Table	Service Water Heating Equipment Performance Requirements	Yes - improved performance per updated table.

In addition to the changes noted above, which are the proposed changes from NECB 2017 to 2020, the models must also take into account the updates between NECB 2015 (currently referenced by BCBC) to NECB 2017. Changes from the current BCBC 2018 (NECB 2015) up to 2020 should all be accounted for. The models must, in essence, go through NECB 2017 to get to NECB 2020 because the only publication relating to NECB 2020 available at the time of writing are the proposed changes since NECB 2017.



Envelope in NECB 2017/2020

One significant change that occurred between NECB 2015 and current editions is the inclusion of additional thermal bridging elements in the calculation of envelope thermal performance. An NECB 2015 compliant wall may have a clear wall performance of, say, R-18 (for climate zone 4) but would not be required to account for certain elements of thermal bridging, such as window transitions. This would lead to that R-18 compliant wall having an actual effective R-value closer to, say, R-10 (depending on details).

As of NECB 2017, and carrying through to NECB 2020, the standard requires a more complete evaluation of envelope thermal performance and the impacts of thermal bridging. Therefore, an R-19.6 wall (NECB 2020 for climate zone 4), must, essentially, have an effective performance of R-19.6.

What looks like an increase from R-18 to R-19.6 is in fact an increase in required performance from effective R-10 (say) to R-19.6.

The actual design implications of this will vary depending on building archetype, designed form, construction type, etc., and the actual level of de-rating may vary substantially.

This has been accounted for in the baseline models, using a de-rating factor in the NECB 2015 baseline walls while using the NECB 2020 baseline walls as-published. Other opaque elements such as roofs typically see less thermal bridging and have been left as is for both baselines (i.e. no de-rating assumed.)

A 40% de-rating factor has been used for all non-combustible construction Part 3 archetypes. Based on our experience, this is representative of typical to somewhat mitigated thermal bridging detailing. A 20%-30% de-rating would be representative of significant mitigation whereas 50%-60% would have been common prior to the current focus on thermal bridging (such as the Building Envelope Thermal Bridging Guide, BC Energy Step Code, and changes to the NECB 2017 and 2020). Examples of typical heat loss via thermal bridging details can be found in Video & Playbook: Thermal Bridging In Net-Zero Energy-Ready Building Design – ZEBx.

The low-rise MURB is intended to represent wood framed construction and a smaller (25%) de-rating factor has been used as typically wood frame buildings see less reduction in performance compared with non-combustible construction.

Heat Recovery in NECB 2017/2020

A second significant change in NECB 2017/2020 is how the requirement for heat recovery is evaluated. Previously, the requirement for heat recovery was calculated as a function of exhaust air temperature, outdoor air temperature, and exhaust airflow. In NECB 2017, the evaluation of heat recovery added parameters for hours of operation, percentage outside air, and total air flow. In some cases, this would lead to the same design requiring heat recovery where it previously did not, where in other cases it would lead to the opposite: the baseline

would no longer need heat recovery in NECB 2020 where it would in 2015. In most cases within this report the two are aligned; where they are not it is noted.

Schedules and Loads

Where default operating schedules or other non-regulated elements such as default internal loads may have changed, the NECB 2017 version (which is assumed to be aligned with what will appear in NECB 2020) was used for all scenarios including the NECB 2015 baseline. Residential loads specifically noted in the City of Vancouver Energy Modelling Guidelines v2, which is referenced in the Step Code, follow those guidelines. All other loads have been updated to the latest available version of NECB default loads.

2.1.2 Other Significant Part 3 Updates

Ventilation Rates to ASHRAE 62.1-2016

Based on discussion with BSSB, it is anticipated that the National Building Code (NBC) 2020 will reference ASHRAE 62.1-2016 Ventilation for Acceptable Indoor Air Quality. Currently in BC, BCBC 2018 references a significantly older version, ASHRAE 62.1-2001 without Addendum N. This report makes the assumption that given the code harmonization efforts, ASHRAE 62.1-2016 would be adopted in BCBC 2022, and ASHRAE 62.1-2016 is used for all Part 3 building models. This would have a significant impact on energy which will vary by building type and space mix, occupant density, and system type selection. In design, project teams could look to reduce the impacts of changing ventilation rates using heat recovery; this will mitigate the energy impact of any changes in rates.

In the archetype buildings used in this study, some archetype ventilation rates increase when updating from ASHRAE 62.1-2001 to 2016, while others decrease.

Multi-unit residential – in our particular unit sizes, depending on occupant densities, ranges from 35-40 cubic feet per minute (cfm) in 2001 to 48-53 cfm per unit in 2016.

Office rates reduce, from (in our case), from 0.43-0.53 cfm/sf for variable air volume (VAV) systems and 0.24-0.3 cfm/ft^2 for dedicated outdoor air systems (DOAS) for ASHRAE 62.1.-2001 (where the difference is due to variations in system effectiveness between VAV and DOAS), down to 0.21-0.23 cfm/sf and 0.12-0.13 cfm/ ft^2 respectively for ASHRAE 62.1-2016.

Retail rates have stayed relatively the same for the mall, but have dropped from 0.296 to 0.231 cfm/ ft^2 for big box.

Hotel rates have decreased by approximately 25%, from an average of 0.174 cfm/ ft^2 to 0.131 cfm/ ft^2.

The above rates should not be considered design guidance and would vary depending on calculation inputs. These rates were used in the energy model study.

City of Vancouver Modelling Guidelines v2

Another change to modelling strategies since the 2018 Metrics Report are the updates to version 2 of the City of Vancouver Energy Modelling guidelines; in particular infiltration rates have changed and now use 0.2 L/s/m^2 of exterior wall area as a constant value. This is used throughout this report.

Climate Zones

Climate zones 4 through 7a were simulated for all archetypes. BC also has regions of climate zones 7b and 8, which were simulated only for the Part 9, low-rise MURB, and hotel archetypes, as new construction of high rise MURB and office are relatively rare in these regions.

2.1.3 Analysis

Part 3 Program Variations

Each archetype has some program variations noted; these are elements that change in the use or programming of the building, rather than being energy related.

Table 2-3. Part 3 Program Variations Summary

Archetype	Program Variations
High Rise MURB	VFAR – full variations not modeled due to simulation time; see Section 6.1.2 for discussion and examples of impact. Suite size – 3 variations modeled, intended to represent small, typical, and large units.
Low Rise MURB	Same variations as high rise MURB.
Office	Office density– two density options; typical (NECB default) and double (heavily occupied office, increased people, ventilation, plug loads). IT loads – see Section 6.1.2 for discussion and examples of impact.
Retail	Big box retail store modeled as 100% retail, or mall modeled with mix of space types (see Appendix A for space mix details).
Hotel	Process loads for laundry changed between electric and natural gas.

Part 3 ECMs

Table 2-4. Part 3 ECM Summary

Archetype	ECMs
High Rise MURB	Walls: R-4, 7, 10, 20, 40 (note R40 walls may not be realistically achievable in a high-rise MURB with balconies). Roof: R-20, 40 Window: USI-2.5, 2, 1.6, 1.2, 0.8 Window SHGC: 0.3, 0.4 Air tightness: Code (City of Vancouver Energy Modeling Guidelines v2 (CoV)), half code, near zero (1/10th of half code value) Window to wall ratio: 20%, 40%, 60% HVAC: electric baseboard, fan coils with standard or condensing boiler or air source heat pump. Heat recovery ventilator (HRV): None, 60%, 80% Domestic hot water (DHW) load savings: 20% (low flow fixtures)
Low Rise MURB	Walls: R-4, 7, 10, 20, 40 Roof: R-20, 40 Window: USI-2.5, 2, 1.6, 1.2, 0.8 Window SHGC: 0.3, 0.4 Air tightness: Code (CoV), half code, near zero (1/10th of half code value) Window to wall ratio: 20%, 40%, 60% HVAC: electric baseboard, fan coils with standard or condensing boiler or ASHP. HRV: None, 60%, 80% DHW load savings: 20% (low flow fixtures), 40% (low flow fixtures + drainwater heat recovery)
Office	Walls: R-4, 7, 10, 20, 40 Roof: R-20, 40 Window: USI-2.5, 2, 1.6, 1.2, 0.8 Window SHGC: 0.3, 0.4 Air tightness: Code (CoV), half code, near zero (1/10th of half code value) Window to wall ratio: 30%, 50%, 70% Lighting savings: None, 25% HVAC: Hydronic variable air volume (VAV), Hydronic fan coil with dedicated outdoor air system (FC + DOAS) Heating: condensing boiler, air source heat pump (ASHP) with boiler top-up HRV: None, 60%, 80% DHW load savings: 20% (low flow fixtures), 40% (low flow fixtures + drainwater heat recovery)
Retail	Walls: R-4, 7, 10, 20, 40 Roof: R-20, 40, 60

	Window: USI-2.5, 2, 1.6, 1.2, 0.8 Window SHGC: 0.4 (only) Air tightness: Code (CoV), half code, near zero (1/10th of half code value) Window to wall ratio: 5%, 20% Lighting savings: None, 25%, 50% HVAC: Unitary gas rooftop unit (RTU), hydronic FC + DOAS with condensing boiler or ASHP with boiler top up HRV: None, 60%, 80% DHW load savings: 20% (low flow fixtures), 40% (low flow fixtures + drainwater heat recovery)
Hotel	Walls: R-5, 10, 15, 20, 30 Roof: R-20, 40 Window: USI-2.5, 2, 1.6, 1.2, 0.8 Window SHGC: 0.4, 0.3 Air tightness: Code (CoV), half code, near zero (1/10th of half code value) Window to wall ratio: 20%, 50% Lighting savings: None, 20%, 40% HVAC: Hydronic VAV, hydronic FC + DOAS with condensing boiler or ASHP with boiler top up HRV: None, 60%, 80% DHW load savings: 20% (low flow fixtures), 40% (low flow fixtures + drainwater heat recovery)

As noted in the table above, it may not be realistically possible to achieve R40 effective wall performance in a high-rise MURB with balconies, even with the use of mitigation measures for thermal bridging in balconies. The realistic performance in our calculations appears to top out in the range of R30-35 using current technology. We have simulated R40 and present those results here to maintain consistency with previous reporting and other archetypes, and to provide a bookend for maximum wall performance impact on energy. The impact of improving wall performance from R30-35 to R40 will generally be minimal, as this is expected to be in the range of diminishing returns for improvements in performance. Therefore the impact on the ability and cost to achieve targets is not expected to be significantly impacted; using an R30-35 wall is expected to give similar energy impacts and act as a practical maximum.

Both low- and high-rise MURBs have been simulated using window to wall ratios of 20%, 40%, and 60%. The results have been filtered using a minimum WWR of both 20% and 40%, and both tables are shown in the appendices. A concern was raised during initial consultations that WWR not be reduced too far for MURBs, therefore both sets of results are presented to represent design flexibility.

Standard efficiency boilers have been excluded from results; these are no longer considered commercially available, and condensing boilers are now typically used in new construction as the minimum efficiency option.

It may not be realistically possible to achieve a near-zero air leakage rate. The air leakage rate modeled is highly dependent on the geometry of the building, with larger buildings with less envelope area (i.e. lower VFAR) typically able to achieve much lower rates for similar styles of construction. The near-zero rate is modeled to provide a lower bookend to whole building energy performance impact. Where 0.1 L/s/m^2 (half of code rate) is able to provide sufficient savings, the near-zero rate has been excluded from results. In a few cases, a leakage rate below 0.1 may be needed at the highest Steps, and in those cases the lower rate is used. These cases are detailed in Appendix C: Detailed Modelling Outputs.

2.2 Part 9 Archetypes

2.2.1 Part 9 Building Archetypes

The same building archetypes as used for the original 2017 and 2018 reports were maintained, and one additional archetype was added, the smaller or laneway single family dwelling. The models are built in HOT2000 version 11.10, and have been run using the Housing Technology Assessment Platform (HTAP) software to simulate a large number of models within a given range of input variations, for example varying the wall R-value, window U-value, and roof R-value, one at a time and in combination to see potential impacts. In addition, variations in window to wall ratio and shape factor were modeled.

EnerGuide Rating System protocols were used in the HOT2000 energy models for the Archetypes. For example, one primary space heating system was used per HOT2000 file, and no supplemental space heating systems such as gas fireplaces, were included. Cooktops and clothes dryers were left on the default of being electric appliances. Any exterior appliances such as gas barbecues, patio heaters or ice melting systems were not included as these are not regulated under the BC Building Code.

The archetypes are outlined in the table below.

Table 2-5. Part 9 Archetypes

Label	Notes	Description	Total Floor Area (sq ft)	Ceiling Heights (ft)- top to bottom	Window Area (sq ft)	WWR
Small SFD	keep as per 2018 study	1 storey on crawlspace	1,100	3/8 (Note: 3 ft represents crawlspace)	144	0.09
Medium SFD	keep as per 2018 study	2 storeys on full basement	2,550	8/8/8	333	0.13
Large SFD	keep as per 2018 study	2 storeys on full basement	5,500	8/8/8	718	0.13
Quadplex	changed to slab on grade with detached parking- note the individual Quadplex units are pretty small already; no room for attached garages	3 storeys, on slab on grade, detached parking	5,526	8/8/8	825	0.16
6 Unit Rowhouse	keep as per 2018 study	3 storeys, on slab on grade	10,300	8/8/8	1750	0.16
10 Unit MURB	keep as per 2018 study	3 storeys, on parkade	17,800	9/9/9	2500	0.25
Laneway SFD	new	2 storeys on slab on grade	750	8/8	225	0.14
Medium SFD with higher WWR	new	increase WWR from 13% to 18%	2,550	8/8/8	461	0.18
Medium SFD with higher WWR	new	increase WWR from 13% to 23%	2,550	8/8/8	589	0.23
Medium SFD with higher SAR	new	increase SAR by 25%, keep WWR same	2,550	8/8/8	333	0.13
Medium SFD with higher SAR	new	increase SAR by 50%, keep WWR same	2,550	8/8/8	333	0.13

Label	Notes	Description	Total Floor Area (sq ft)	Ceiling Heights (ft)- top to bottom	Window Area (sq ft)	WWR
Large SFD with higher WWR	new	increase WWR from 13% to 18%	5,500	8/8/8	994	0.18
Large SFD with higher WWR	new	increase WWR from 13% to 23%	5,500	8/8/8	1270	0.23
Large SFD with higher SAR or SVR	new	increase SAR by 25%, keep WWR same	5,500	8/8/8	718	0.13
Large SFD with higher SAR or SVR	new	increase SAR by 50%, keep WWR same	5,500	8/8/8	718	0.13

2.2.2 Changes to BCBC Section 9.36

The proposed changes to BCBC Section 9.36 currently are relatively minor and we do not anticipate significant impacts on the base costs; these changes have been incorporated into the base case used for costing in this study.

There is a change to 95% minimum Annual Fuel Utilization Efficiency (AFUE) for furnaces. However, this is already captured in energy efficiency regulations so suppliers are currently selling 95% AFUE furnaces, and therefore there is no cost premium.

Window maximum USI-values are expected to decrease from 1.80 to 1.61 via the Energy Efficiency Standards Regulation effective January 1, 2022. Because this regulation is separate from the BC Energy Step Code or 9.36, and has not yet taken effect as of the time of conducting simulations, the base case remains at 1.80 in the current study.

2.2.3 Variations and ECMs

Shape Factor

New, modified versions of the medium and large single family dwelling archetypes were created for this study in order to evaluate the impact of increasing the building surface area to floor area ratio (SAR) in Part 9 buildings. For both the medium and the large single family dwelling archetypes, the SAR was increased by both 25% and by 50%, while keeping the window to wall ratio at the original value in the archetype. The SAR was increased by increasing the length of the exterior walls, keeping the height of exterior walls and the overall volume of the buildings the same. This approach resulted in an increase in the complexity of the building envelope geometry typical of complex buildings with a high form factor ratio.

Window to Wall Ratio

New, modified versions of the medium and large single family dwelling archetypes were created for this study in order to evaluate the impact of increasing the window to wall ratio (WWR) in Part 9 buildings. For both the medium and large single family dwelling archetypes, the WWR was increased from 13% to 18%, and from 13% to 23%. The window to wall ratio was increased by increasing the size of the windows, thus increasing glazing by orientation in the same proportion as the initial window layout.

ECMs

The below ECMs were analyzed. Some exceptions or limitations of combinations were applied in order to limit the number of runs and amount of data, for instance not combining the worst airtightness with the best windows or vice-versa. In addition, any individual ECMs that do not meet the base case for a particular climate zone or archetype were excluded, so for example if the base case requires R10 under slab in a colder climate, options below R10 were not run for that climate.

Note that this list also includes the base case values for initial starting runs. The base case descriptions are available in Appendix A.

Table 2-6. Part 9 ECMs

Component	Recommended Options	# of Choices	Change from 2018 Study
Airtightness (Air changes per hour (ACH)@50Pa)	3.5, 2.5, 1.5, 1.0, 0.6	5	same
Above Grade Wall Effective R value	16, 18, 22, 26, 30, 40	6	reduced from 8
Below Grade Wall Effective R value	11, 17, 21, 25	4	same
Under Slab Effective R value	0, 10, 14, 20	4	same
Floor Over Unheated Space Effective R value	28, 32, 36	3	reduced from 4
Ceiling Below Attic Effective R value	40, 50, 60, 80	4	reduced from 6
Flat Roof Effective R value	28, 32, 36	3	not used in 2018
Windows (USI/SHGC)	1.80/0.25, 1.60/0.25, 1.40/0.25, 1.40/0.35, 1.00/0.25, 1.00/0.35, 0.80/0.25	7	same
DHW Systems	electric tank (0.82 EF), natural gas tank (0.67 EF), natural gas tankless (0.95 EF), ASHP integrated tank (1.90 EF)	5	same
Drain Water Heat Recovery Systems (recovery efficiencies)	none, 30%, 55%	3	reduced from 5

Component	Recommended Options	# of Choices	Change from 2018 Study
Space Heating Systems	natural gas furnace (95% AFUE), electric baseboard, cold climate ASHP (heating seasonal performance factor (HSPF) 7.1) for Climate Zones 6, 7A, 7B and 8 with electric resistance back up heat if needed, regular heat pump for Climate Zones 4 and 5 with natural gas furnace back up (95% AFUE)	4	Reduced from 5
Ventilation Heat Recovery (SRE @ 0C)	none, 65%, 75%, 85%	4	reduced from 5

Table 2-7. Methodology to limit combinations of data

Limitations/exceptions:
No solar photovoltaic (PV) or solar domestic hot water (DHW) heating
No district energy systems
No geo exchange systems
No gas heat pumps
No P9.11 systems due to modelling challenges
Methodology to limit combinations of ECMs to save time running HTAP and reduce data:
Airtightness no tighter than 1 level tighter than required by Step; i.e. no tighter than 1.5ACH@50Pa for Step 3
Archetypes that use electric baseboard heat for their base case will not change to natural gas furnace; only upgrade to heat pumps
Higher window performance levels reserved for higher Steps
Drain water heat recovery systems reserved for Step 3 and higher
85% SRE HRV reserved for Step 4 and higher
Heat pumps for space heating reserved for Step 4 and higher
Heat pumps for DHW heating reserved for Step 4 and higher
*Certain combinations of ECMs, such as pairing the worst windows with the best airtightness, will be omitted. These omitted options target combinations that would use the best of one option with the worst of another; while these combinations may be used on actual designs based on project priorities, they are not considered as representative of typical scenarios. In addition, on many projects it may make sense to use heat pumps for lower Steps; these were omitted as they were expected to have higher cost at the lowest Steps for the archetypes modeled.

Climate Zones

The full range of BC's climate zones are modeled for all archetypes, providing a wide range of results including those in colder climate zones.

Table 2-8. Part 9 Climate Zones and City Locations

Climate Zone	Heating Degree Days	Weather File
4	up to 3000	Vancouver (2825 HDD)
5	3000-3999	Summerland (3350 HDD)
6	4000-4999	Cranbrook (4400 HDD)
7A	5000-5999	Fort St. John (5750 HDD)
7B	6000-6999	Fort Nelson (6710 HDD)
8	7000+	Uranium City, Sask. (7500 HDD)

*Note that HOT2000 has certain limitations of available weather files; the files above were selected to be representative of the climate zone but may not represent the largest population or construction centres in that climate zone due to availability of weather files.

2.2.4 Part 9 Metrics

Modelling Rowhouse Buildings

Rowhouse-type buildings such as the quadplex and 6-unit rowhouse archetypes, which consist of living units side by side, will be modelled as whole buildings for the purpose of this study. This follows the requirements in the BC Energy Step Code: *where a building contains more than one dwelling unit, the requirements of this Subsection shall apply to the energy performance of the building and not to individual dwelling units.*

The "BCESC Compliance Report Calculator" tool was not specifically used for this study since it requires manual input of data which would prove to be far too labor intensive for this study requiring automation of many thousands of different HOT2000 energy model runs. Spreadsheet analysis and macros were developed which performed similar calculations but allowed for automatic calculations for large numbers of results rather than using the manual calculator. In addition, the rowhouse-type buildings were modeled in HOT2000 as whole buildings with the appropriate amount of individual units and corresponding base loads included, and these HOT2000 models were then run with the various ECM's

% Better Envelope Metric

The percent better envelope metric is new since the 2018 costing study. This metric is often applied to housing that is larger, or has more complex or articulated shapes and higher SAR. A list of the percent better envelope metric target values for each archetype and for each climate zone are outlined in Table 2.9.

TEDI Adjusted Metrics

TEDI targets are calculated on a prorated scale; this is a new approach to TEDI targets since the 2018 costing study. TEDI targets are now calculated factoring in the specific heating degree days of the particular city location chosen to represent each climate zone. Note that the adjusted TEDI targets listed later in this report are not applicable to the entire climate zone, but rather for only the particular city location chosen.

MEUI Adjusted Metrics

MEUI targets are determined based on the heated floor area of the building, and whether the building has at least 50% of its floor area served by space cooling equipment. This results in different MEUI targets for different sizes of archetypes even for the same climate zone. When the particular ECM package includes a heat pump, which would also be able to provide air conditioning, it is assumed it was assumed that the heat pump would be used to air condition at least 50% of the building, and the corresponding MEUI target was used as part of the step code target values for that particular archetype period.

Table 2-9. Step Code Targets (BCBC 2018)

				Step 3							Step 4							Step 5					
Archetype	Floor Area (sq m)	Climate Zone (HDD)		ACH@50Pa	% Better than ERS Ref House	MEUI- no cooling (kWh/sq m*yr)	MEUI if >50% cooling (kWh/sq m*yr)	Adjusted TEDI (kWh/sq m*yr)	Envelope Performance Over ERS Ref House (%)		ACH@50Pa	% Better than ERS Ref House	MEUI- no cooling (kWh/sq m*yr)	MEUI if >50% cooling (kWh/sq m*yr)	Adjusted TEDI (kWh/sq m*yr)	Envelope Performance Over ERS Ref House (%)		ACH@50Pa	% Better than ERS Ref House	MEUI- no cooling (kWh/sq m*yr)	MEUI if >50% cooling (kWh/sq m*yr)	Adjusted TEDI (kWh/sq m*yr)	Envelope Performance Over ERS Ref House (%)
Laneway House	70	4 (Vancouver 2825 HDD)		2.5	20	100	128	36.5	10%		1.5	40	80	108	26.5	20%		1.0	N/A	55	83	18.3	50%

3 Costing

3.1 Context

COVID-19

The effects of the COVID-19 coronavirus pandemic and related supply disruptions and shortages have largely been excluded from this analysis as they are anticipated to be relatively short term; and likely to not impact incremental costs (e.g. while they may impact the base price of a window, the difference between a typical and premium window is likely to remain relatively consistent). Some costs have been requested from local suppliers; we have requested current rough order of magnitude costs which may make some allowance for current market conditions.

Historical Changes

As was discussed in the 2018 Metrics Report, historically, the cost premiums of high-performance building components have gone down over time, as the technology develops and as the market matures.

Synergies

The costs within this report do not make use of the synergies that may be available and may assist project teams on an individual basis to optimize their designs. For example, air-source heat pumps are assumed to be sized entirely for heating and all cost is assigned as a heating ECM; in reality they may be sized for cooling and the only additional cost may be adding a heat pump internal heat recovery function, particularly in a case where peak heating loads have been substantially reduced through envelope and heat recovery measures. (Note that this heat recovery function differs from air-to-air heat recovery such as ERVs or HRVs; it is an equipment characteristic of a heat pump that would allow the cooling equipment to also provide useful space heating.)

Baseline for Costing Comparison

The baseline ($0 incremental capital cost) case for the study is the current BCBC 2018, which references NECB 2015 and the current 9.36. ECMs are assigned an incremental cost, and the total incremental cost for a particular simulation is calculated in comparison with that baseline. In some cases, a cost savings may be evaluated.

3.2 Methodology/Sources

Base Construction Costs

Base construction costs were sourced from the 2021 Altus Canadian Construction Guide, for both Part 3 and Part 9 construction. It was noted that the 2021 Altus Canadian Construction Guide specified the construction costs it lists were collected in the year 2020, and so represents a period in time both just before the initial impact of the COVID-19 pandemic began and a period of time in the first few months of the initial impact of the COVID-19

pandemic. Thus the costs it lists are neither exclusively pre pandemic nor are they exclusively during the pandemic.

For both the Part 3 and Part 9 building archetypes, the average of the high and low cost values was used as the base construction cost value.

Cost Database

RSMeans 2021 data was used to source most passive cooling measures, and to confirm costing for Part 3 ECMs including envelope measures and HRVs.

Local Contractors, Suppliers, and Consultants

Part 3 costing also relied on discussions with local contractors, suppliers, and consultants to obtain design and cost options from a number of sources and to obtain up to date local data. These values were vetted using RSMeans and in comparison with the 2018 Metrics Report.

2018 Metrics Report

In a small number of cases, in particular for roof insulation for Part 3 buildings, we have used the costs from the 2018 Metrics Report, applying 2% inflation per year over the last 3 years. Roof insulation in particular is a relatively small component of costs, and this is not expected to introduce significant error.

Average of 10 Best

In order to avoid using outlier values, the results presented for costs (for incremental capital cost, NPV, and GHG abatement costs) in this report use the average of the 10 best, rather than the single best option. "Best" has been considered in terms of ICC, NPV, and cost of GHGI abatement for both Part 3 and Part 9.

LEEP

Part 9 modelling is conducted using HTAP, which builds in NRCan's LEEP database for costing. The costing included in LEEP is dated early 2020, and was developed by NRCan in consultation with local builders.

The construction cost information collected from builder companies of various sizes located in the Lower Mainland, Vancouver Island, and the Okanagan as part of the early 2020 LEEP work were incorporated into the HTAP programming used for this study. The costing information collected in early 2020 just predates the COVID-19 pandemic beginning, and represents typical construction costs not including the effects of the pandemic.

3.3 Regional Costs

Costs are multiplied by a location multiplier; this multiplier is maintained from the 2018 Metrics Report. Both base costs and ECM costs apply the multiplier.

Table 3-1. Climate Zone Cost Multipliers

Climate Zone	Cost Multiplier
4	1.000
5	1.073
6	1.126
7A	1.502
7B	1.502
8	1.502

3.4 Costing Assumptions

Discount Rate

A 3% discount rate is applied. A brief sensitivity analysis was conducted and is shown in Section 6.1.5.

Utility Rate

For non-residential Part 3 buildings, utility rates use BC Hydro's Large General Service for electricity and Fortis BC's Rate 2 (<2000 GJ/year) rate for natural gas. Actual utility rate structures for different building sizes or services may vary, however the rates used can apply to any of the Part 3 archetypes. MURBs are modeled using residential rates as per below.

Utility cost escalation rate is modeled at 2%. Utility rate details for Part 3 are available in Appendix A.

For Part 9 buildings, residential rates for both electricity (Hydro rates) and natural gas (Fortis BC rates) were used. Utility cost escalation rate is modeled at 2%.

Table 3-2. BC Hydro Electricity Residential Rates

Name	Applicability	Energy Cost ($/kWh)	Energy + Carbon Tax ($/kWh)
Tier 1	0 – 1,350 kWh/month	0.09410	0.09460
Tier 2	1,350+ kWh/month	0.14100	0.14150
Meter Fixed Fee	Meter Fixed Fee	$75.92 (annual fixed fee)	

Table 3-3. Fortis BC Natural Gas Residential Rates (Part 9)

Name	Applicability	Energy Cost ($/GJ)	Energy + Carbon Tax ($/kWh)
Consumption Charge	Energy use	9.265	11.5775
Meter Fixed Fee	Meter Fixed Fee	$153.88 (annual fixed fee)	

Incentives

Incentives may be available for certain systems included as energy conservation measures in this study. Incentives have not been included in the cost analysis, as the available incentives may differ over time, or based on project ownership, location, and other factors.

Carbon Pricing:

Currently the models assume that federal government commitments will remain as is; with carbon pricing hitting $170/ton in 2030. After 2030, the current model assumes a slightly slower but continued linear increase, hitting $300 at the final year of our 20-year analysis period. The impact on average natural gas cost over the 20-year period is shown below, based on the current GHG factors contained in the City of Vancouver Energy Modelling Guidelines v2.0.

The same approach was taken for Part 9 and Part 3.

Table 3-4. Carbon Pricing Scenarios

Years	Discount Rate	Escalation	Carbon Pricing	Average NG Cost over analysis period, in 2021 dollars
20	3%	2%	$45 in 2021 $50 in 2022 and after	12.75
20	3%	2%	$45 in 2021 $50 in 2022 Linear increase to $170 in 2030 Stay at $170 to 2040	15.98
20	3%	2%	$45 in 2021 $50 in 2022 Linear increase to $170 in 2030 Escalate to $300 at final year of 20-year period (linear increase $13/year 2030 through 2040)	17.16

NPV Calculation

The NPV calculation is conducted over a 20-year timeframe. This maintains a consistent life cycle replacement timeline for all major components included in this analysis. This approach is consistent with the 2018 Metrics Report, and further discussion on this approach can be found there.

Detailed Costs

Detailed cost data is available in Appendix B for Part 3. ECM costs for Part 9 are integrated into the detailed modelling results for each scenario in Appendix C; this breaks out the base building and ECM cost for each ECM in each modeled option.

4 Carbon Emissions

4.1 Operating Carbon

Operating carbon refers to the ongoing CO_2 emissions related to the energy use of the building. The modelling analysis in the study focusses on electricity and natural gas, as the two most common energy types used by buildings in BC.

For this analysis, the greenhouse gas emissions factors from the City of Vancouver Modelling Guidelines v2.0 are used:

Natural Gas: 0.185 kgCO_2e/kWh

Electricity: 0.011 kgCO_2e/kWh

A sensitivity analysis has been conducted to understand the potential impact of varying the energy source and grid mix.

Energy Supply

The electric grid in BC includes the Integrated grid (supplying southern and western BC), the Fort Nelson grid (northeast BC), and community generating stations for isolated grid communities (throughout BC). The Fort Nelson grid and the community generating may have very different GHG emissions factors than the Integrated grid.

In 2020, the Fort Nelson grid had approximately 13.2 times higher emissions than the Integrated grid. In 2012, the Fort Nelson grid represented approximately 0.3% of total BC Hydro service area sales, according to BC Hydro's Electric Load Forecast, Fiscal 2013 to Fiscal 2033. At the time of the report, the Fort Nelson grid's demand was expected to grow, however, this still represents a relatively small proportion of connections. While these need to be accounted for in the policy, either an exclusion or simply applying the same GHGI factors and thereby requiring similar measures to the rest of the province, could be considered without significantly impacting the overall impact of the targets. The same BC Hydro report also noted that a significant portion of load on the Fort Nelson grid came from large industrial accounts, which would not be impacted by Step Code targets.

Table 4-1. 2020 Electricity GHG Emission Intensity Factors

Grid	Tonnes CO_2 equivalent per Gigawatt-hour
Integrated grid	40.1
Fort Nelson grid	530

Source: https://www2.gov.bc.ca/gov/content/environment/climate-change/industry/reporting/quantify/electricity

In addition to electricity and natural gas, other fuels or energy sources, such as district heating, diesel, biomass, or photovoltaics (among others) would have significant differences in operating carbon compared with buildings using electricity or natural gas. These additional energy or heating sources can have significant variations in greenhouse gas emissions factors even within the same category of supply; for example a district energy system could combine low-GHG technologies and renewable electricity generation, could use conventional fossil fuel supply and have high transmission losses, or could be somewhere in between.

Further, there are a number of possible sources for green energy emissions factors which may be treated differently by different programs. These variations are not addressed within this report, which focusses on fuel sources that are widely applicable throughout BC.

A summary of the emissions factors discussed is shown below.

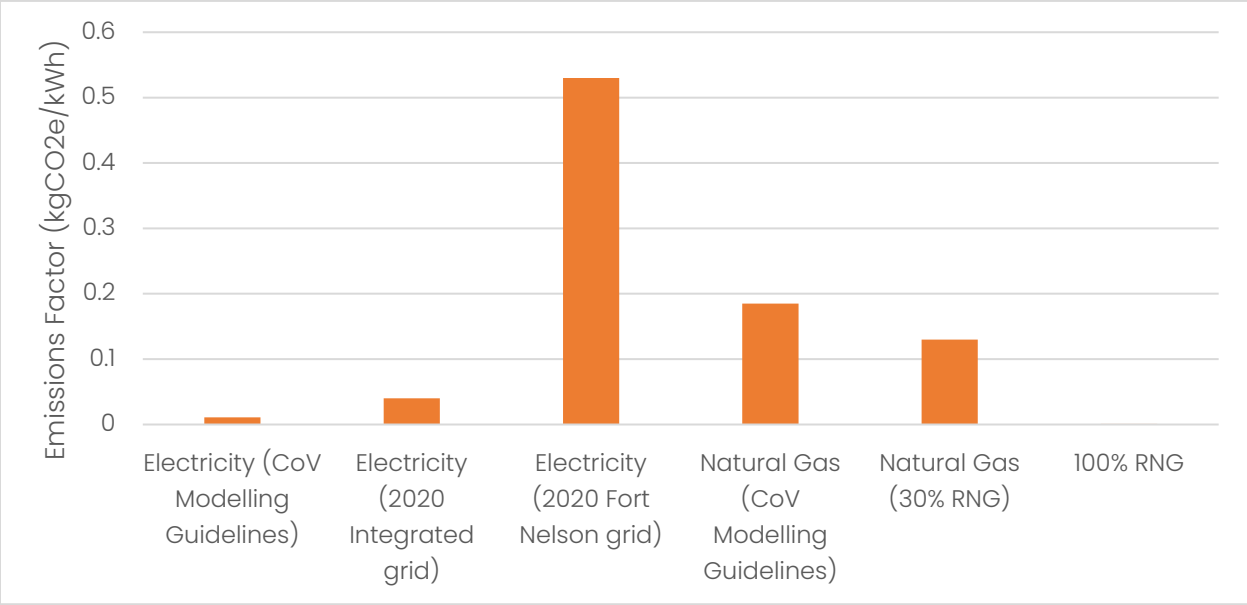

Figure 4-1. Greenhouse Gas Emissions Factors

Where a certain percentage of RNG is shown in the graph, (e.g. Natural Gas (30% RNG)) this indicates that 30% of the total supply of natural gas (either to the building or to the overall utility supply network) consists of RNG. This has been shown as an effect of approximately a 30% reduction in the emission factor compared with a fully natural gas option.

Energy Conservation Measures

The energy conservation measures (ECMs) analyzed within this report will impact greenhouse gas emissions; reducing energy use will naturally reduce operating emissions as well. Further, for a fossil fuel heated building, a focus on TEDI reductions will target one of the largest sources of GHG emissions in the building, heating.

However, the impact of ECMs will typically be smaller than the impact of energy sources. In BC's relatively low-carbon electricity grid, ECMs would need to save in the range of 80-95% of heating energy to achieve the carbon equivalent to a switch from natural gas to electricity.

To provide one example of impact, the below figure shows a MURB in climate zone 4 going from R-4 walls to R-40 walls, leading to an 18% TEUI and 41% TEDI savings. This nets a 30% GHGI savings. Leaving the walls at R-4 but switching to electric baseboards leaves TEDI unchanged and provides some TEUI savings (due to both boiler efficiency and fan energy in this particular mechanical system setup of boiler with fan coil units), but leads to 58% GHGI savings – nearly double the savings of the wall ECM.

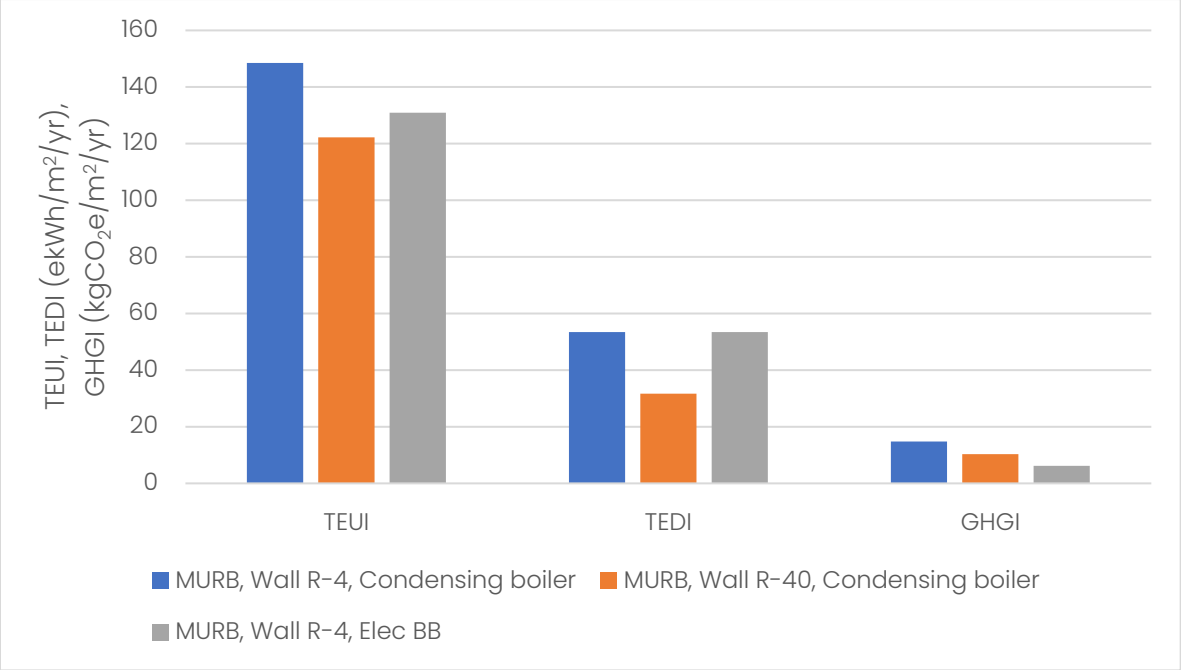

Figure 4-2. ECM impact on GHGI

However, it is not generally feasible or advisable to simply fuel switch with no attention to ECMs; attention must be paid to both. In general, electric heating and electric hot water heating may be provided either through electric resistance (such as electric baseboards or electric resistance DHW heaters), or through heat pump or related technologies such as variable refrigerant flow.

Electric resistance heating has low installation costs (e.g. electric baseboards), but higher operating costs than natural gas. Actual cost differentials vary based on utility rates and future carbon tax scenarios, but are generally between 1.5 and 3 times as costly to operate in terms of utility costs for heating energy. The potential increase in operating cost can be offset by energy savings in the design, by reducing TEDI by a similar proportion. As an example, this might represent a TEDI improvement from 40, meeting Step 2, to 20, meeting Step 3 and approaching Step 4, in a MURB in climate zone 4. This is expected to be achievable using the ECMs outlined in this report.

Alternatively, projects may look at heat pump or similar options such as variable refrigerant flow (VRF). These have a higher operating efficiency, with coefficients of performance (COPs) typically ranging between 2 and 4 (which can be thought of as an efficiency of 200% - 400%). This brings utility costs into the same range as natural gas heating, and in fact leads to lower

heating utility costs within the next 10 years as carbon taxes increase to the federal commitment of $170/tonne in 2030.

> Both energy conservation measures and low-carbon energy supply must be considered in combination to achieve significant reductions in greenhouse gas emissions.

However, heat pumps and similar technologies tend to have higher capital costs, and may require more floor area within the building to locate equipment. In this case, ECMs that reduce heating load are important in order to reduce the size of equipment, to reduce capital costs and space requirements.

Finally, the demand on the electrical grid and distribution infrastructure should be considered in consultation with the electricity supplier, both within the Integrated grid and local grids.

Technology Drivers

A synergy that some design teams may find useful is the potential to use heat pumps or VRF systems to provide both heating and cooling. While the use of mechanical cooling is typical in commercial buildings, it is not a given in residential buildings in BC. A desire by teams to provide mechanical cooling, or a need to do so based on overheating risk may drive decision making.

Domestic hot water heating is still predominantly natural gas in our experience on recent new construction projects. While electric resistance and heat pump options are available in the BC market, and heat pump options are currently incentivized by utility rebate programs, adoption is still in the relatively early stages. With increasing carbon taxes, continued technology development, and increasing market penetration, it appears likely that this will continue to grow in adoption.

4.2 Embodied Carbon

Embodied carbon is not considered within the scope of this report, which focusses on greenhouse gas emissions related to ongoing utility use in the building. Embodied carbon is an important consideration and should not be ignored; an overall life cycle balance minimizing greenhouse gas emissions should be struck.

As energy use and operating greenhouse gas emissions in buildings drop, embodied carbon becomes a larger share of the overall life cycle carbon impact of the building. As such, the impacts of policies targeting operating carbon should also consider the impacts on embodied carbon in buildings.

The study "Implications of the BC Energy Step Code on GHG Emissions" (Integral Group, 2019) notes several significant impacts on greenhouse gas emissions:

1. Reducing embodied carbon will require a focus on the materials of the building (such as the City of Vancouver's life cycle analysis requirements).
2. Methane leaks in natural gas distribution systems are noted as significant contributors to global warming, and while renewable natural gas can mitigate the impacts of this,

the projected supply of 30% will not significantly displace natural gas by 2030 and risks locking buildings to heating systems run primarily on conventional fossil fuel based systems until their replacement.

3. Electric heat pumps contain refrigerants, many of which have high global warming potential. This can be mitigated by regulating the refrigerant types that can be used, but should be considered and reported.

The current report analyzes the impact of the envelope on operating energy and GHG emissions. There is a concern that at high insulation levels, increasing insulation further could lead to increased embodied carbon, and that particularly in a scenario where heating is supplied by BC's relatively low emission electricity grid, there may be cases where additional insulation has a net negative life cycle carbon impact. This can be mitigated through materials choices and a focus on thermal bridging to achieve maximum utility of increased insulation.

5 Overheating Risk Analysis

The City of Vancouver Energy Modelling Guidelines v2.0 include a requirement to conduct an overheating risk analysis, and a methodology for doing so, for buildings that are not designed with a full mechanical cooling system. Most commercial buildings are typically designed with a full mechanical cooling system, potentially also employing passive cooling measures to reduce loads, and are not analyzed in this study. However, MURBs are frequently designed without full mechanical cooling, and may rely on passive cooling strategies to maintain occupant comfort.

Part 3 MURBs are modeled within this portion of the study, and a variety of passive cooling measures are considered.

The methodology defined in the City of Vancouver Energy Modelling Guidelines v2.0 is followed in this study, and requires modellers to assess the number of hours that exceed the comfortable indoor air temperature. Comfort conditions are defined based on the ASHRAE 55-2020 80% acceptability limits, on a monthly basis, and depend on the temperature of the outdoor air over the previous month. A limit of 200 hours per year is set, as well as a limit of 20 hours for vulnerable populations.

5.1 Weather

The passive cooling analysis uses both 2020s and 2050s future projected weather files from the Pacific Climate Impacts Consortium (PCIC) (https://services.pacificclimate.org/demo/wx-files/app/).

Over time, the temperature is expected to increase, though the rate may vary depending on how climate change progresses. Energy modelling uses "typical weather year" files developed statistically based on the previous 30 years of actual observed weather. The CWEC 2016 files currently in use are in fact a backwards-looking amalgamation of data going back as far as 1984, when the climate was very different than today's. The weather files used for this overheating risk portion of the study use forward looking scenarios estimating potential projections in the 2020s and 2050s for typical weather years. Climate zone 8 (Yellowknife) uses CWEC 2016 weather files only, as projected 2020s and 2050s files are not available.

Extreme events, such as heat waves, are not represented in available future-projected weather files to evaluate extreme conditions under which life safety issues may occur. These extreme weather events are expected to occur with increased frequency and severity as climate change continues to progress.

As anticipated, over time the number of warm hours increases compared with the currently used typical weather file. The CWEC 2016 weather file includes 6 hours over 27°C for Vancouver, increasing to 58 hours in the 2050s file. For Fort St John, there are 41 hours over 27°C in the 2016 weather file, but 137 hours in the 2050s file. 27°C is used as an example threshold here to illustrate the increasing typical temperatures; bin analysis for the number of hours between 25°C and 30°C are shown below at 1°C increments.

However, it is important to note that these 2020s and 2050s future looking weather files still fundamentally look at "typical" weather for energy modelling purposes. Extreme events, such as heat waves, are still not adequately represented to evaluate extreme conditions under which life safety issues may occur. These extreme weather events are expected to occur with increased frequency and severity as climate change continues to progress.

Table 5-1. Hours above temperature bin analysis for future projected weather, CZ4 and 7a

	Vancouver			Fort St. John		
Hours above:	CWEC 2016	2020s	2050s	CWEC 2016	2020s	2050s
25°C	31	50	155	108	140	248
26°C	14	30	92	67	98	199
27°C	6	13	58	41	63	137
28°C	0	5	29	11	32	95
29°C	0	0	14	3	10	58
30°C	0	0	6	0	3	37

*The above table does not capture extreme weather events, and looks at typical weather years only.

Table 5-2. Hours above temperature bin analysis for 2020s projected weather, all zones

	2020s					
Hours above:	Vancouver (CZ4)	Kamloops (CZ5)	Prince George (CZ6)	Fort St. John (CZ7a)	Fort Nelson (CZ7b)	Yellowknife (CWEC 2016, CZ8)
25°C	50	668	108	140	139	63
26°C	30	544	77	98	82	44
27°C	13	436	60	63	51	20
28°C	5	338	41	32	30	16
29°C	0	265	27	10	9	6
30°C	0	208	19	3	0	0

*The above table does not capture extreme weather events, and looks at typical weather years only.

The most mild location of those considered in this study in terms of overheating risk based on the 2020s projected weather is Vancouver in climate zone 4.

Climate change is increasing the frequency and severity of unusual weather events, such as the heat dome that recently affected much of BC with record breaking hot weather. In that heat wave, there were 40 hours above the acceptability limit outdoors (using the SFU weather station), over the course of 4 days, exceeding in a single event the annual overheated hours limit for vulnerable populations, and leading to a significant number of deaths in BC.

The below graph shows outdoor air temperature, whereas comfort conditions look at indoor temperature. Passive design measures such as night pre-cooling may help to mitigate the impact of outdoor air temperature on the indoor environment, although in this particular event the night temperatures were also too high to provide meaningful night pre-cooling.

However, a significant portion of passive cooling design measures rely on outdoor temperatures being relatively comfortable. The absence of good cooling design may also lead to indoor air temperatures being significantly higher than ambient outdoor air temperatures, putting occupants at elevated risk.

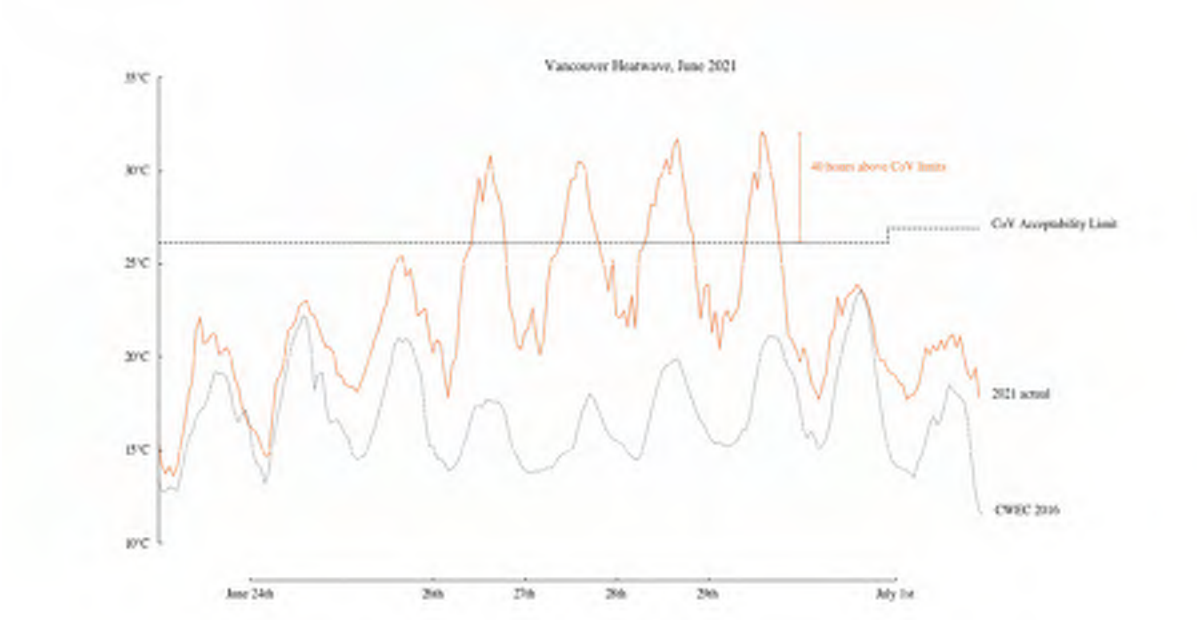

Figure 5-1. June 2021 heat wave (SFU campus weather station) vs. CWEC 2016 weather file

The frequency and severity of forest fires is also expected to increase. Passive cooling strategies which rely on the use of unfiltered outdoor air, such as operable windows, should anticipate periods of unavailability due to poor or dangerous outdoor air quality.

The figure below shows wildfire smoke events in 2020 in Vancouver, plotted with CWEC 2016 and future shifted 2050s weather. While the major smoke events in 2020 did not coincide with the hottest periods of the typical weather year in that case, the longest smoke event, which would have prevented most occupants from opening windows for several days, occurred within weeks of one of the hottest periods of the year.

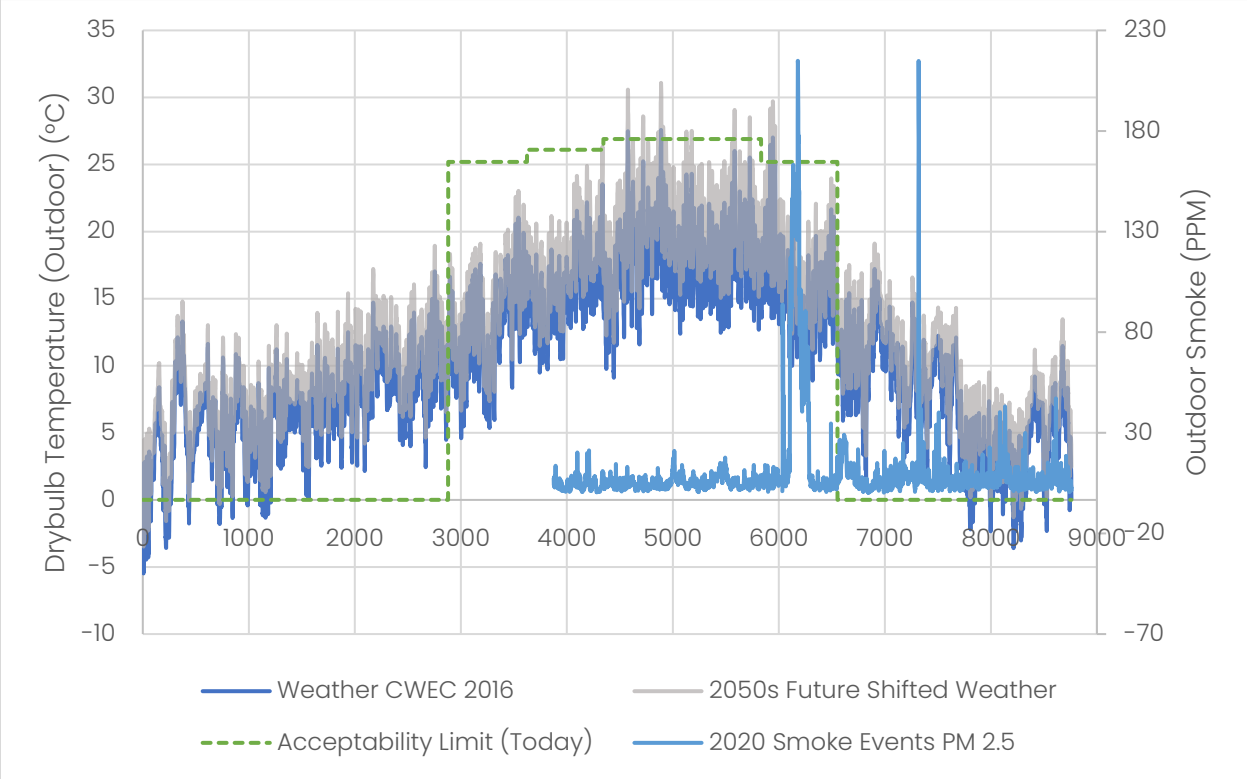

Figure 5-2. Smoke events in 2020 compared with weather

As extreme weather events become more common, the effectiveness of some passive cooling measures will be reduced during certain events. However, good passive cooling design, coupled with active cooling measures, becomes even more critical to achieving occupant comfort and mitigating risk to occupants. Simply using mechanical cooling and ignoring passive cooling design would increase risk to occupants during power outages or equipment failure, particularly if these occur during increasingly common extreme weather events. Both passive and active measures should be considered.

5.2 Passive Cooling Measures

A number of passive cooling measures are considered within this analysis.

From a modelling perspective, the same model as was used for the high- and low-rise MURBs has been used, however it has been modified to add a natural ventilation analysis as well as the passive cooling measures analyzed. This adds simulation computing time to the model as the software must perform more complex calculations, therefore the passive cooling measures analysis is performed separately from the ECM analysis discussed elsewhere in the report. Passive cooling measures are in large part independent from the ECMs analyzed elsewhere, if applied appropriately. For example, while operable windows tend to have higher U-values than fixed windows, achieving an overall U-value matching the ECM levels analyzed

can still be targeted. HRV bypass can be applied on low- or high-efficiency HRVs. Lighting is modeled with no lighting savings in the passive cooling measures analysis, which is the worst case scenario in terms of internal heat gains from lighting. One exception of note is that shading systems designed as a passive cooling measure may increase TEDI, in the event that the shading systems not only block the undesired summer or shoulder season sun, but also block desired winter solar gains that assist in reducing heating loads and providing occupant indoor environmental quality. There exist a number of design measures such as movable shades that can be used to reduce this effect.

However, the building envelope, window to wall ratio, and solar heat gain coefficient, which were all part of the ECM simulation, may have a significant impact on passive cooling and have also been included within the passive cooling analysis. Envelope has been simulated using three packages, low-, mid-, and high-performing, described below, intended to provide a bookend analysis of potential impact.

For this overheating analysis, envelope thermal performance and air tightness ECMs were combined into a single measure, described as low-, mid-, and high-performance levels. A low-performance envelope would meet Step 2 for a MURB in climate zone 4 for a VFAR of 0.6. A mid-performance envelope would meet Step 2-3 in climate zone 4. A high-performance envelope for this analysis would meet Step 4 in all climate zones, though naturally all of the Step levels would be dependent on additional factors such as shape, window to wall ratio, HRVs, etc.

One further element which has not been fully investigated as part of this study are the impacts of internal gains, such as plug loads, cooking loads, etc. These are modeled using City of Vancouver Modelling Guidelines v2.0 values and schedules, which are generally aligned with NECB internal loads. Internal loads can have a significant impact on overheating. Some time shifting or load reductions may be able to be done by occupants, such as avoiding cooking during the hottest periods of the day, however such strategies may not be viable for all occupants. In addition, much higher internal loads could be seen in reality, which would increase overheating.

Table 5-3. Passive Cooling Variations

Variation	Analysis Range
Envelope	Low = R-4 walls, R-20 roof, USI-2.5 windows, code infiltration Mid = R-10 walls, R-40 roof, USI-2.0 windows, code infiltration High = R-20 walls, R-40 roof, USI-1.2 windows, near-zero infiltration
Window to wall ratio	20%, 40%, 60%
Weather	2020s, 2050s future shifted PCIC typical operating year files (RCP8.5)

Table 5-4. Passive Cooling Measures

Measure	Analysis Range
SHGC	0.2, 0.4
Night pre-cool	16°C, 18°C
HRV Bypass	Yes, No
HRV Boost	Yes (20%), No (note only provided if there is also an HRV bypass)
Exterior Shading	0.6m overhang above window (all facades), fin 0.6m depth spaced approximately every 5m (south and west façades), movable exterior shades (e.g. roller shades)
Operable windows	0%, 5%, and 20% of equivalent window area if WWR is 40%

In several cases, the model was re-run using inputs that would not be appropriate for determining TEDI or TEUI for compliance purposes. For example, night pre-cool does not significantly assist cooling if the daytime setpoints immediately turn on heating to warm the space up. We would typically expect occupants to turn the thermostat down on a seasonal basis to allow for some night pre-cool and for the space to be gradually warmed by the sun and outdoor temperatures. As such, TEDI and TEUI are not reported in combination with overheated hours. A discussion of the impacts of the passive cooling measures modeled on TEDI and TEUI is provided in the results discussion section.

Unmet hours are analyzed as those not meeting the indoor maximum temperatures described by month in the City of Vancouver Modelling Guidelines, and are summed for individual zones. The zone with the largest number of overheated hours is taken as the hours overheated for the building.

Unmet hours are reported based on a simplified ASHRAE 55-2020 80% acceptability limit based on their adaptive comfort model. The limits are calculated by calendar month rather than as a rolling average of the previous up to 30 days. This methodology is in line with the City of Vancouver Energy Modelling Guidelines, and allow simpler calculation and reporting.

The 80% acceptability limits are applicable only for months when the mean outdoor air temperature is above 10°C, as such some climate zones have fewer applicable months than others. All analysis ignores localized areas of potential discomfort within a zone, which cannot be assessed using a typical energy model.

Table 5-5. Acceptability limit maximum indoor air temperature by month: simplified ASHRAE 55

Max. indoor air drybulb temperature (°C)	Vancouver	Kamloops	Prince George	Fort St John	Fort Nelson	Yellowknife
May	25.2	25.9	24.4	24.4	NA	NA
June	26.1	26.7	25.6	25.7	25.9	25.6
July	26.9	28.1	26.1	26.5	26.6	26.7
August	26.9	28.1	25.9	26.1	25.9	25.9
September	26.1	26.1	NA	24.5	NA	NA

While previous recent outdoor temperature does play a role in comfort, research also indicates that there are maximum acceptable or safe indoor air temperatures in which other factors play a role. BC Housing's Builder Insight 19 discusses a recent study (Kenny, Flouris, Yagouti, & Notley, 2019) by the University of Ottawa attempting to establish maximum indoor temperature conditions for human life safety. The conditions were found to vary based on individual characteristics, but a trend of 26°C was suggested, and BC Housing recommends reporting the number of hours above 26°C. The number of hours over 26°C is reported in the analysis.

The results of the analysis are shown in Section 6.1.4 in the Results section of the report.

6 Results

6.1 Part 3

6.1.1 Impact of NECB 2020

The increased stringency of NECB 2020, which is intended to be adopted in the upcoming version of the BC Building Code, leads to a need for increased stringency of the BC Energy Step Code minimum performance. The below is a summary of our recommendations, which is followed by a more in-depth comparison of NECB 2015, NECB 2020, and current Step Code targets.

The goal is for the new minimum target to require better performance than NECB 2020; and in addition, for performance to be at least 20% better than the 2018 BCBC.

Table 6-1. Recommendations for Updated BC Energy Step Code Targets – Part 3

Archetype	Recommendation for New Minimum Step
MURB (high- and low-rise)	Step 2
Office	Step 2
Retail	Step 2
Hotel	Step 2

Our recommendations are based on the following:

Incremental Approach

Our recommendation is to take an incremental approach, increasing the minimum by a single Step, rather than leapfrogging to the highest Step.

1. This aligns with previous messaging and industry perceptions around the future progression of the BC Energy Step Code and its development.
2. Projects that have variations such as shape, size, and occupant density, may have limitations in being able to achieve higher Steps, compared with the archetypes modeled in this report. This further supports the incremental approach proposed, increasing the stringency gradually, as long as the NECB 2020 minimum performance is shown to be met. While limited analysis on certain variations have been done here, the impacts of these variations should be considered as an area for further study.

Meeting NECB 2020

Our recommendation takes an approach of balancing the TEDI and TEUI metrics that appear in the BC Energy Step Code.

1. We have confirmed that based on the archetypes modeled, the NECB 2020 baseline would need to be improved upon in some way in order to meet Step 2 targets; in other words a Step 2 building would generally meet the NECB 2020 in terms of either TEDI or

TEUI or both. The percentage improvement of a Step 2 building versus NECB 2020 would vary but an improvement is generally supported by the archetype models.

2. A slight increase in stringency of Step 2 TEUI requirements could also be considered for office and retail archetypes. Average TEDI of Step 2 is better than NECB 2020 baseline TEDI, however average TEUI for those two archetypes would not.

3. It should be noted that it cannot be said with 100% confidence that all designs meeting Step 2 would be better than NECB 2020; this is true of current Step Code targets as well and becomes increasingly true as stringency of the base code increases. This is the nature of comparing absolute and baseline targets. Baselines exclude the impacts of, for example, building size and shape, by comparing the proposed design to one of the same size and shape. However, absolute targets such as TEUI and TEDI allow credit or penalty for these design factors. As such, we can compare the impacts on particularly archetypes (as is done in this study) and variations on those archetypes, but a fully generalizable comparison is not possible.

The table below shows the average TEUI and TEDI savings for each modeled Part 3 archetype across the full range of modeled climate zones. The savings show the savings of a building minimally meeting the Step targets compared with NECB 2020. All archetypes on average meet the NECB 2020 at Step 2 in terms of either TEUI or TEDI. Office and retail archetypes, on average, do not meet the NECB 2020 TEUI based on Step 2, but do meet if TEDI is considered. Both archetypes have relatively favorable shapes; if a less favorable (higher VFAR) shape was considered, both would show additional savings compared with the baseline. In that case, both the baseline and proposed would use a higher proportion of heating in comparison with other end uses, and the TEDI savings would be magnified, along with the more efficient than baseline provision of heat, leading to greater savings versus the baseline.

MURB and hotel show savings compared with NECB 2020 at Step 2 for both TEDI and TEUI. NECB 2020 considers only TEUI as a compliance metric; however we have suggested considering TEDI as part of this analysis as this is a significant metric within the BC Energy Step Code.

Step 4 is not considered below as this is not expected to be considered as a potential minimum Step for any archetype.

Negative values indicate that the Step considered is less stringent than the NECB 2020 baseline.

Table 6-2. Savings of Steps 2 and 3 Targets vs NECB 2020

Archetype		Average TEUI Savings	Range of TEUI Savings	Average TEDI Savings	Range of TEDI Savings
MURB (high- and low-rise)	Step 2	12%	-3% to 27%	27%	4% to 47%
	Step 3	20%	8% to 35%	45%	20% to 63%
Office	Step 2	-22%	-28% to -14%	6%	-22% to 36%
	Step 3	4%	2% to 7%	38%	19% to 58%
Retail	Step 2	-16%	-28% to 0%	16%	-15% to 52%
	Step 3	13%	2% to 9%	39%	9% to 68%
Hotel	Step 2	29%	22% to 34%	51%	31% to 67%
	Step 3	39%	35% to 43%	62%	54% to 71%

In addition, a 20% savings of the new minimum Step target vs. NECB 2015 is desired. Only TEUI and TEDI are considered; however new proposed GHGI targets will also add a relevant dimension to the targets and are expected to lead to substantial and targeted GHG reductions.

For all archetypes except retail, Step 2 TEUI and TEDI both meet the 20% savings threshold compared with NECB 2015. Retail is very close with TEDI (19% average savings), but ranges from 10% higher than NECB 2015 to 9% savings for TEUI. As noted above, retail uses a very favorable shape (VFAR), and would show additional savings compared with the baseline if a less favorable shape were selected for the analysis due to magnifying the TEDI savings and more efficient heating system savings. Given the TEDI savings, anticipated GHG savings with new targets, and the variability of savings based on building size and shape, climate zone, and other characteristics, an incremental improvement of the minimum to Step 2 for all building types continues to be recommended.

Table 6-3. Savings of Steps 2 and 3 Targets vs NECB 2015

Archetype		Average TEUI Savings	Range of TEUI Savings	Average TEDI Savings	Range of TEDI Savings
MURB (high- and low-rise)	Step 2	24%	6% to 40%	42%	16% to 58%
	Step 3	31%	17% to 46%	56%	30% to 71%
Office	Step 2	24%	21% to 26%	50%	38% to 63%
	Step 3	40%	37% to 42%	67%	59% to 75%
Retail	Step 2	-1%	-10% to 9%	19%	-9% to 53%
	Step 3	24%	17% to 36%	41%	9% to 68%
Hotel	Step 2	39%	34% to 43%	56%	38% to 69%
	Step 3	48%	45% to 52%	65%	58% to 73%

Additional archetype-by-archetype exploration of the NECB 2015, 2020, and Step levels is below.

MURBs

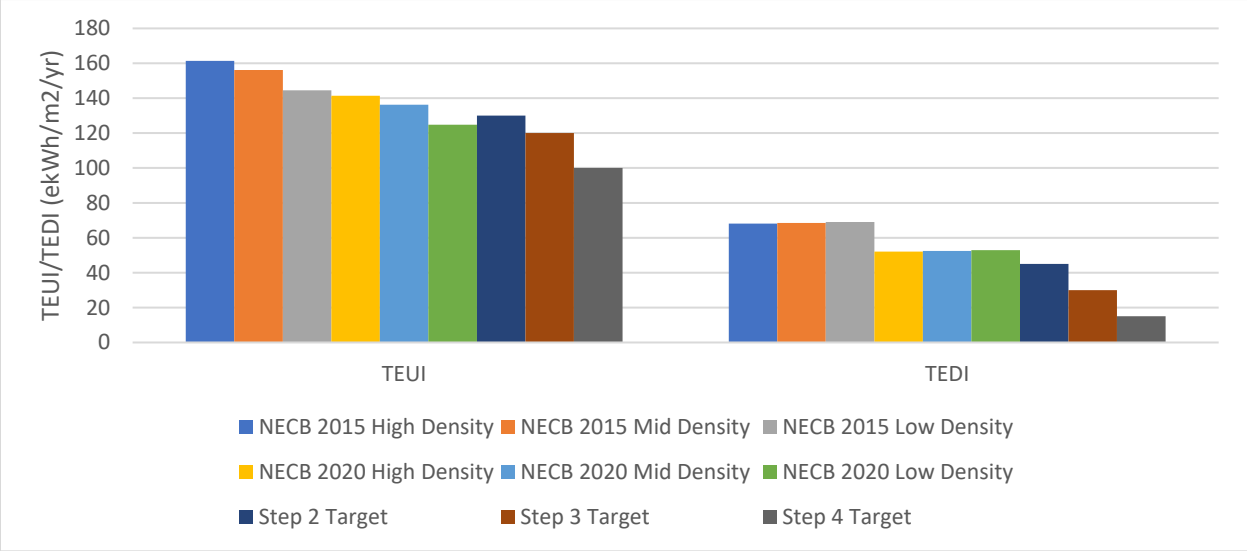

Figure 6-1. Comparison of NECB 2015 and 2020 and current targets for Baseboard MURBs in Climate Zone 4

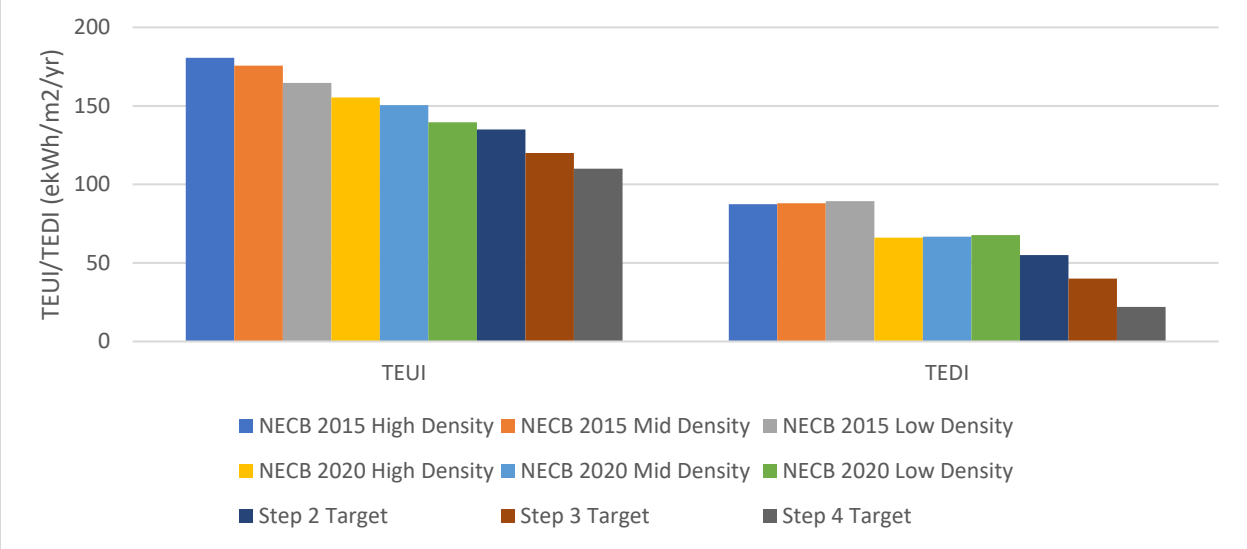

Figure 6-2. Comparison of NECB 2015 and 2020 and current targets for Baseboard MURBs in Climate Zone 7a

The above figure looks at the difference between the current targets for climate zones 4 and 7a, and the updated NECB 2015 and 2020 MURB baseline models. It uses the high-rise MURB archetype with electric baseboards, at VFAR 0.6 (the scenario shown for high-rise MURB in Section 8.5 of the 2018 Metrics Report), and with a range of densities, from smaller unit sizes to larger unit sizes. As noted elsewhere in the current report, the energy results for the high-rise and low-rise (6-storey) MURB are the same and the same targets apply for both; the costs differ as we look at wood frame construction for the low-rise MURB and non-combustible construction for the high-rise MURB.

For climate zone 4, the figure shows that the TEUIs for NECB 2020 for MURBs are approximately 20 ekWh/m²/year lower than the comparable density case for the NECB 2015 TEUI, approximately a 12-14% decrease. In all but the lowest density case, NECB 2020 TEUIs are higher than the Step 2 target TEUI. In the lowest density case, the NECB 2020 TEUI is higher than the Step 3 target.

For TEDI in climate zone 4, the NECB 2020 for MURBs is approximately a 16 ekWh/ m²/year reduction compared with NECB 2015, representing approximately a 23% drop. All NECB 2020 TEDIs are higher than the Step 2 target. In climate zone 7a, a similar pattern is seen, with reductions from NECB 2015 to NECB 2020, then to Steps 2, 3, and 4.

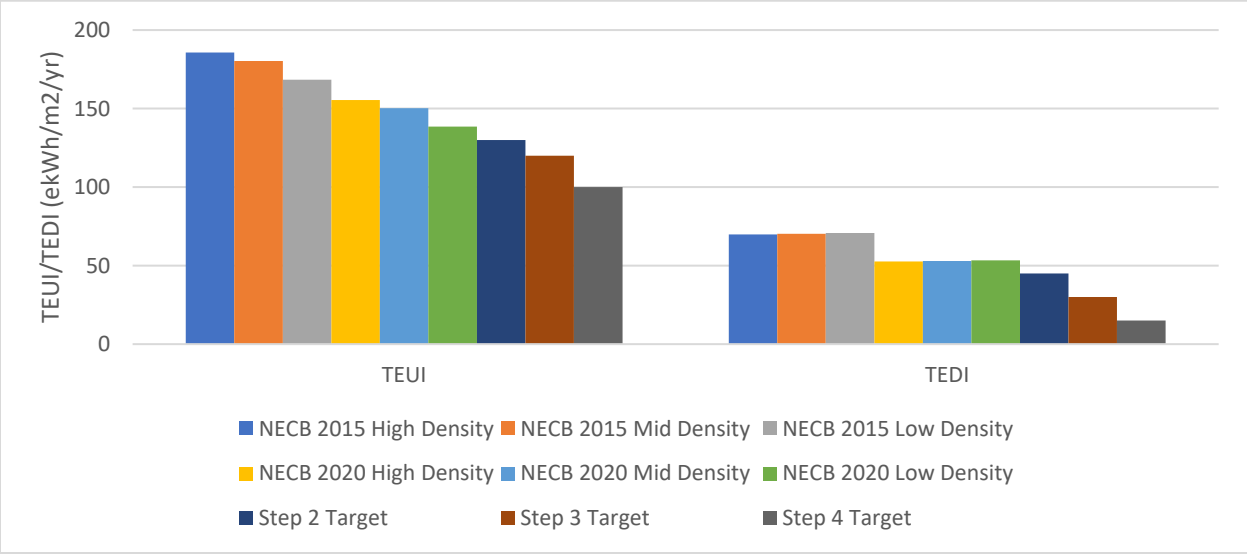

Figure 6-3. Comparison of NECB 2015 and 2020 and current targets for fan coil MURBs in Climate Zone 4

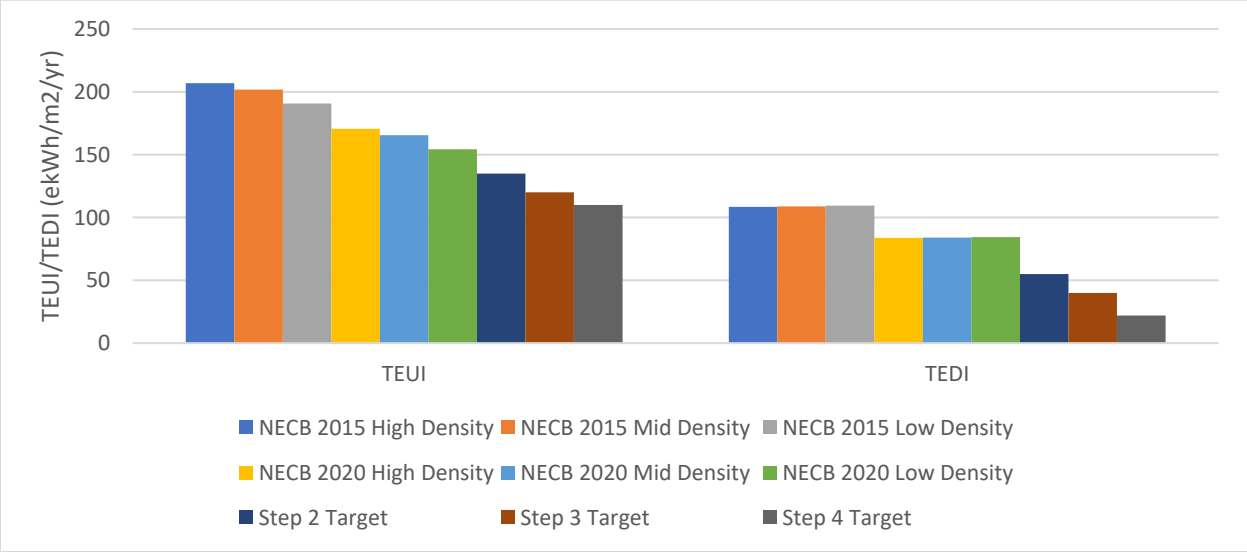

Figure 6-4. Comparison of NECB 2015 and 2020 and current targets for fan coil MURBs in Climate Zone 7a

In the case of the MURB archetype that uses fan coils as the mechanical system rather than electric baseboards, the baseline TEUI increases compared with the baseboard case due to added fan power and added heating (this can be offset in actual design by design elements such as ECM fans and central ASHP heating.) In all cases for the fan coil baseline model, the NEBC 2020 TEUIs and TEDIs are lower than NECB 2015 but higher than Step 2.

Our recommendation for MURBs is to use Step 2 targets as the new minimum. The Step 2 targets meet the criteria of having lower TEUI and TEDI than the NECB 2020 models, for all of the variations in occupancy modeled.

Offices

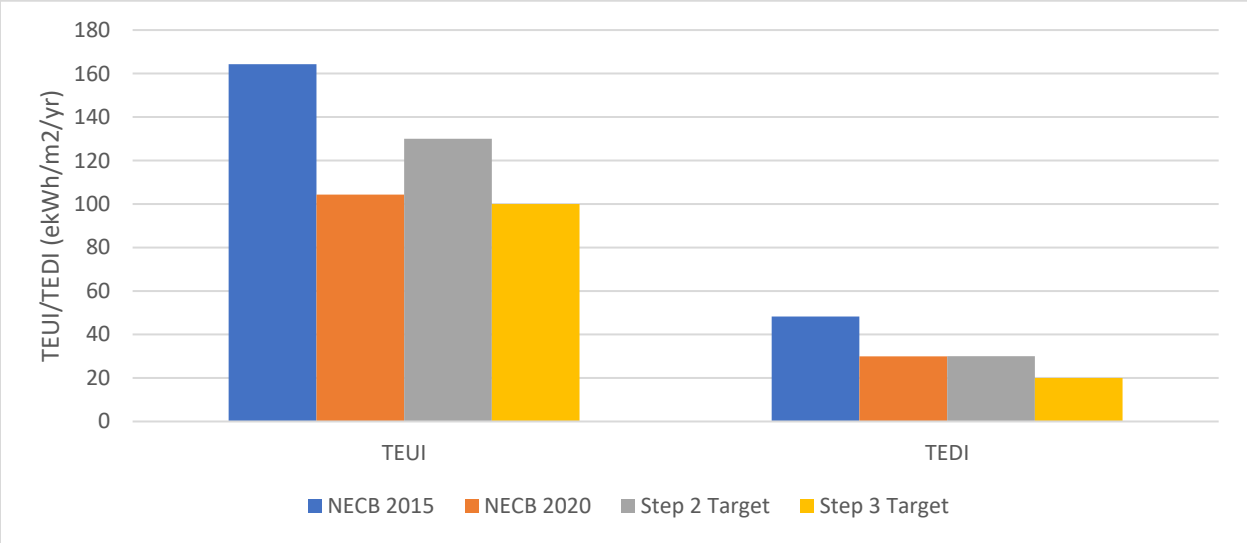

Figure 6-5. Comparison of NECB 2015 and 2020 and current targets for offices with default occupancy for Climate Zone 4.

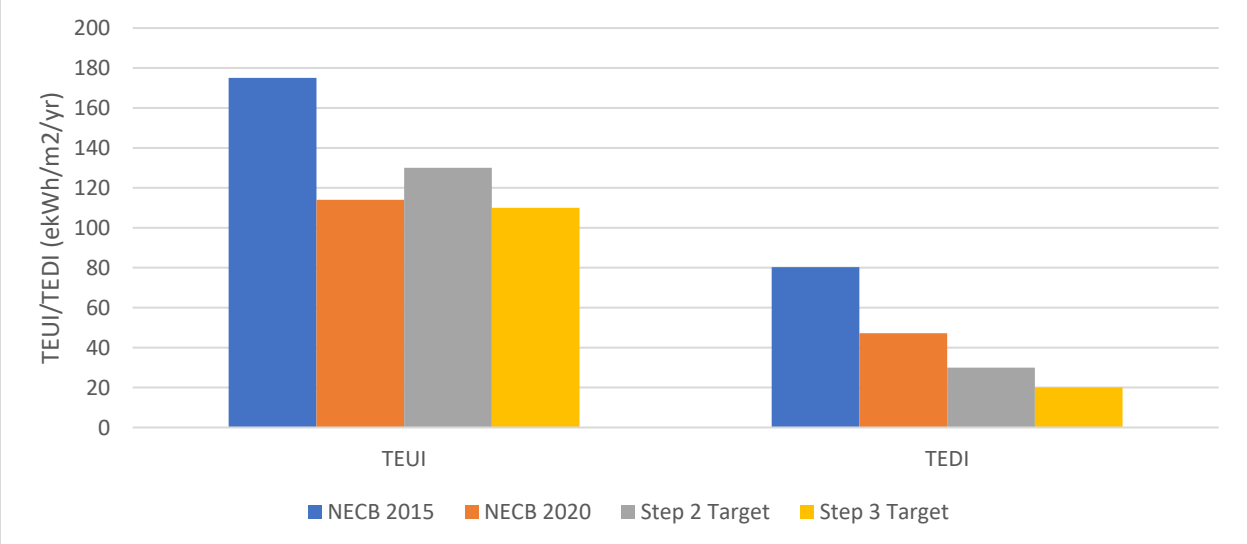

Figure 6-6. Comparison of NECB 2015 and 2020 and current targets for offices with default occupancy for Climate Zone 7a

For the office with typical occupancy, there is a significant drop in TEUI between NECB 2015 and 2020. This is due to reductions in heating and cooling, combined with smaller reductions in lighting and fans. Approximately 3/4 of the heating energy reduction is due to the addition of a warmest reset control and the change to no longer require a 2 L/s/m^2 minimum in NECB 2020. These two changes also account for approximately half of the reduction in cooling. Other changes between the two include envelope improvements as well as reductions in lighting power, which will both affect heating and cooling.

The TEUI of the NECB 2020 minimum is slightly above that of Step 3 but well below the Step 2 target. TEDI has dropped by 18 ekWh/m^2/year between NECB 2015 and 2020; this represents approximately a 38% drop. The TEDI of the NECB 2020 baseline is 30, equal to the Step 2 target.

Our recommendation for offices is to use Step 2 targets as the new minimum. Designs meeting Step 2 targets would generally meet NECB 2020 in terms of either the EUI or the TEDI, though some exceptions were noted. It should be noted that NECB compliance is based on total energy use rather than TEDI, so if the Province requires further confidence that NECB compliance via the performance path could be met, TEUI should be the deciding factor. However, TEDI is a significant metric within the BC Energy Step Code, and our proposed approach has balanced the two metrics. It should also be noted that projects that have variations in shape, size, and occupant density, may have limitations in being able to achieve higher Steps compared with the archetypes modeled in this report. An incremental approach of increasing the minimum by a single Step is therefore recommended.

Retail

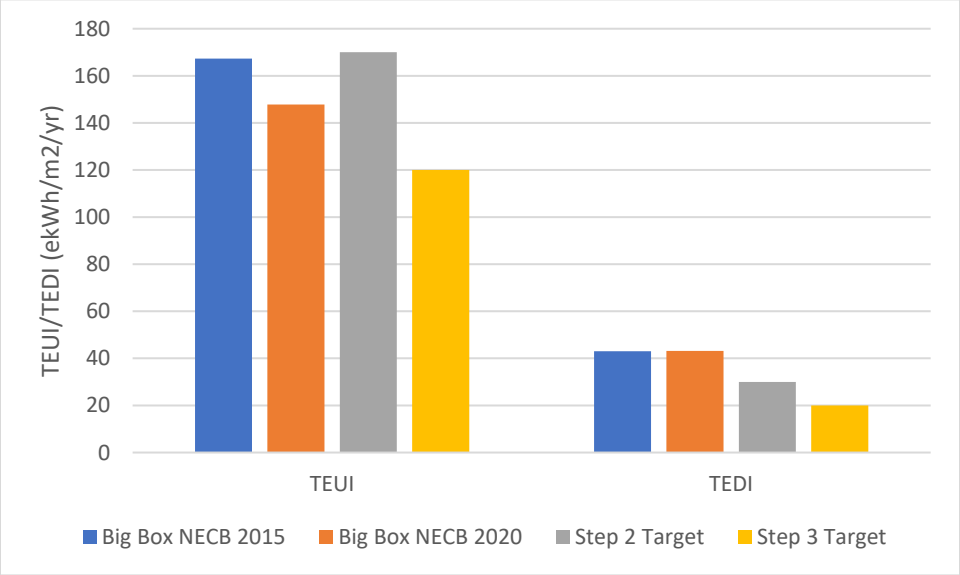

Figure 6-7. Comparison of NECB 2015 and 2020 and current targets for big box retail for Climate Zone 4.

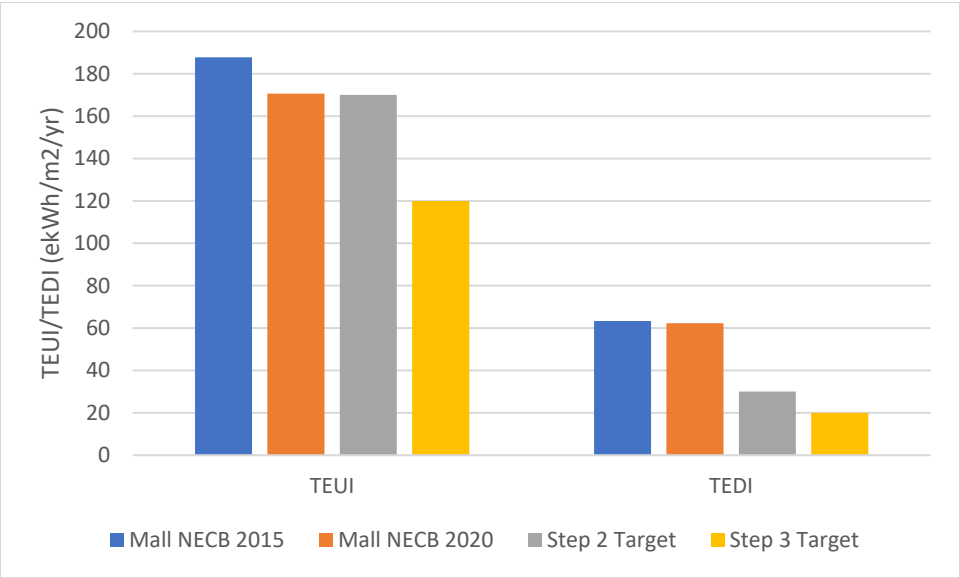

Figure 6-8. Comparison of NECB 2015 and 2020 and current targets for mall for Climate Zone 4.

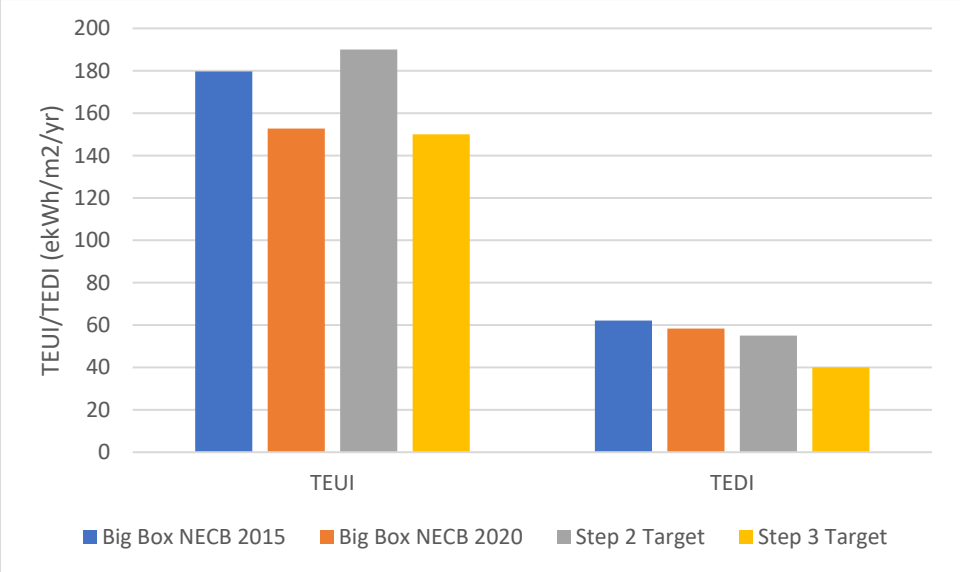

Figure 6-9. Comparison of NECB 2015 and 2020 and current targets for big box retail for Climate Zone 7a.

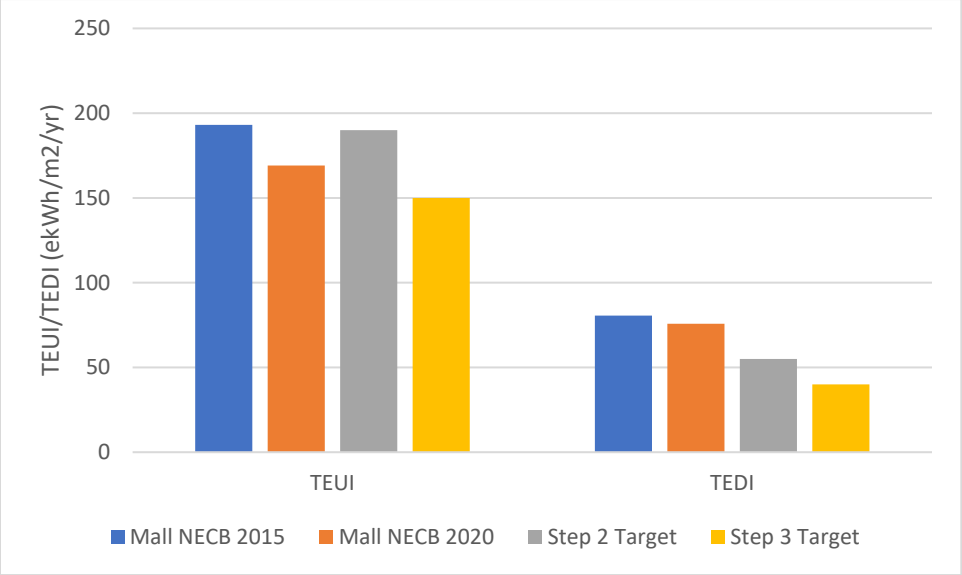

Figure 6-10. Comparison of NECB 2015 and 2020 and current targets for mall for Climate Zone 7a.

In all but one case shown above for retail, the TEUI for NECB 2020 falls between Steps 2 and 3, and the TEDI is higher than Step 2. In the other case shown above, the TEUI is almost identical to Step 2 (171 vs 170). The TEDI has slight reductions between NECB 2015 and 2020, while TEUI is reduced, primarily due to reduced lighting power density and improvements in heating efficiency.

As with the office, our recommended approach for retail is to set the new minimum to Step 2. The reasoning is similar to that for offices: either the TEDI or the TEUI for an NECB 2020 baseline must be beat in order to meet Step 2 targets. As above, our proposed approach looks at both TEDI and TEUI; NECB would look only at total energy use and the Province could prioritize this if required. Also similar to offices, shape factor, size, and other program variations may impact ability of particular buildings to achieve significantly higher targets and an incremental approach is recommended.

Hotel

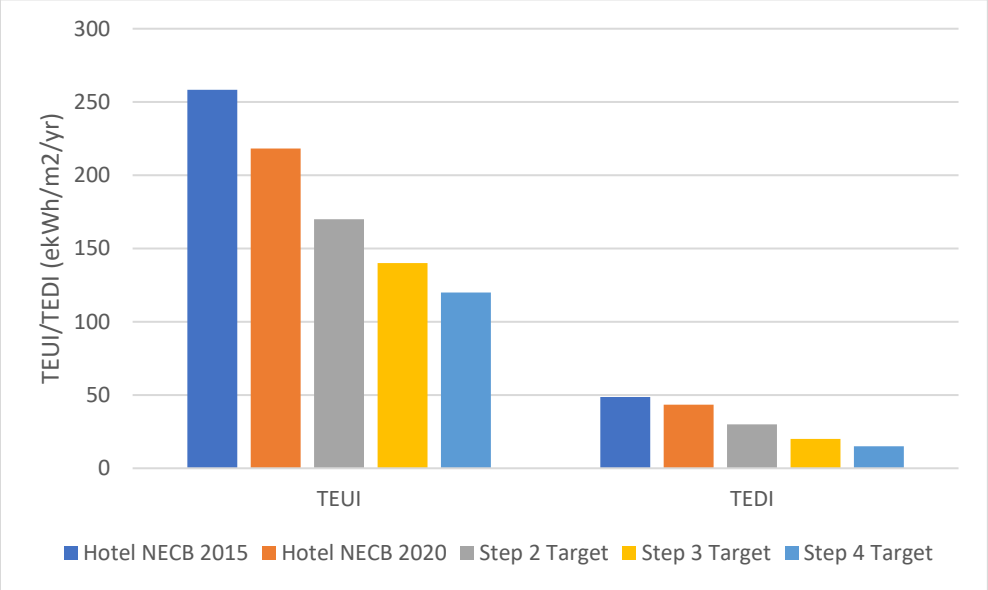

Figure 6-11. Comparison of NECB 2015 and 2020 and current targets for Hotel for Climate Zone 4

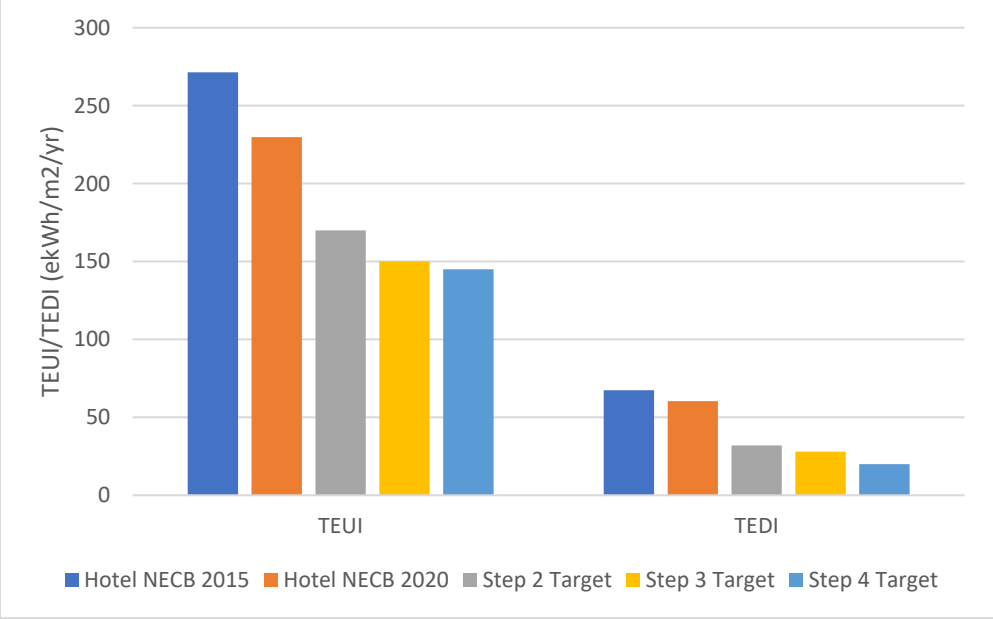

Figure 6-12. Comparison of NECB 2015 and 2020 and current targets for Hotel for Climate Zone 7a

For climate zone 4, hotel TEUI drops by approximately 15%, while TEDI drops by approximately 10%, from NECB 2015 to NECB 2020. The Step 2 targets fall 22% and 30%, respectively, below the NECB values. This allows for on-site laundry, pool, and commercial kitchen, as was done in the 2018 Metrics Report. The climate zone 7a results show a similar pattern, with reductions from NECB 2015 to 2020, and further reductions into Steps 2 to 4.

Our recommended approach for hotels is to set the minimum to Step 2. As with other archetypes, Step 2 targets would require improvements beyond the NECB 2020 minimum; in the case of hotels this is true for both TEUI and TEDI based on the archetype modelling conducted.

Summary of % Difference

The NECB baselines in the study have some range of variation, even within the same archetype, due to changes in program (e.g. big box retail vs mall), or changes in mechanical systems (e.g. boiler vs ASHP). Further, the TEUI and TEDI differentials between the baselines may not be consistent – one NECB 2020 baseline may have 15% better TEUI but 30% better TEDI than NECB 2015, or vice-versa. The tables below summarize the percentage differences between NECB 2015, 2020, and Steps 2 and 3. Example climate zones 4 and 7a are shown below.

In updating to NECB 2020 from NECB 2015 as the base code, the base code becomes more efficient, with average energy performance increases of:

12% for retail

11% for hotel

33% for office

15% for MURB

The detailed breakdown of the different scenarios modeled is shown in the table below.

Table 6-4. MURB Percentage variation between NECB 2015, 2020, and Steps 2 and 3

6.1.2 Program Variation Impacts

Office IT Loads

IT loads such as servers can impose a significant load on the overall energy use (TEUI) of the building. Such loads can be designed to have minimal impacts on TEDI and GHGI, by isolating them from other areas of the building such that a targeted cooling system provides cooling to server rooms rather than relying on the overall building system.

Both the load and the building size will influence the TEUI impact. Unlike many design elements, building size and IT load are not correlated. A small office building housing a call centre would be likely to have a very high IT load and very high TEUI as a result. A larger office housing engineering firms may have no concentrated server loads.

As an example, a 40 kW IT load was added to the archetype office, along with a dedicated cooling system, and resulted in an EUI increase of 27. Depending on the deficit imposed and level of performance targeted, it may be possible to make up such an increase using envelope, mechanical, and lighting measures discussed in this study; as one example the difference between R-20 walls, USI-0.8 windows, half of code infiltration rate, and ASHP, would make up a 27 TEUI difference between that scenario and one using R-4 walls, USI-2.5 windows, code infiltration, and condensing boilers.

In terms of target setting in the context of NECB 2020, an office with an IT load would increase the TEUI of the baseline. In our example above, an increase of 27 TEUI would mean that the NECB 2020 baseline with IT load would be higher than the Step 2 targets in all of the cases shown in Section 6.1.1, and would require ECMs to meet Step 2 targets. This supports the incremental approach suggested in Section 6.1.1 to set Step 2 as the new minimum target. Step 2 could still be readily achieved using reasonable ECMs; Step 3 is still barely achievable for our study archetype with significant ECMs, however there is concern about the potential impacts for buildings with less favorable shapes or sizes.

Shape and Massing of MURBs (VFAR)

The shape and massing of multi-unit residential buildings was discussed in depth in the 2018 Metrics Report, and was noted to have a significant impact on TEDI and energy use. This shape factor is measured as the “vertical surface to floor area ratio” or VFAR. VFAR focusses on the vertical surface area rather than the total surface area, as in the BC context for MURB buildings, most heat loss occurs in the vertical surface areas.

Building codes that use reference or baseline buildings, such as NECB and ASHRAE, render the shape factor compliance neutral by using a reference building with the same geometry as the proposed. However, for an absolute target based code like the BC Energy Step Code, the form factor of the building can be optimized to improve performance (or can make the targets more difficult to achieve for a poor performing form factor).

The 2018 Metrics Report found that for a sample of high- and low-rise MURBs in BC and across Canada, most projects fell within the range of 0.5 to 0.65 VFAR. Floor plate size and level of articulation were found to be the principal factors affecting VFAR.

The following graphic from the 2018 Metrics Report shows the impact of VFAR, with other design elements held constant for a Step 2 MURB. The impact of doubling VFAR, from 0.5 to 1, more than doubles the TEDI. If VFAR of 0.6 is considered as typical, reducing VFAR to 0.5 would allow 20% TEDI savings. Design measures to be considered here include more compact or square shapes, reduced articulation, and larger floorplates.

Consistent with the 2018 report, the results in this study use VFAR 0.6 for MURBs.

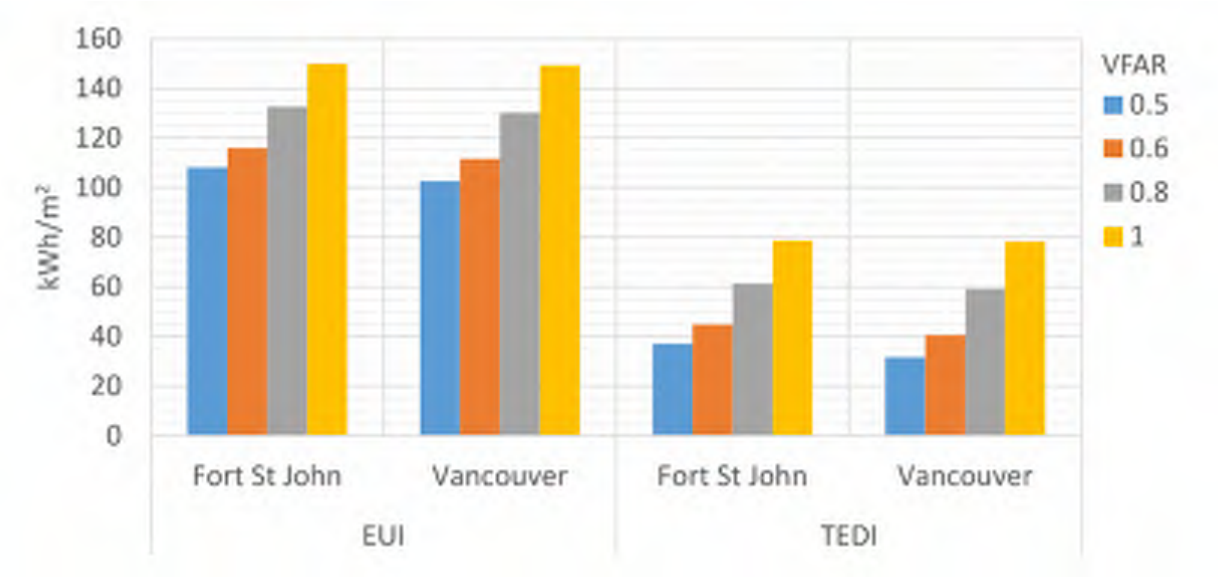

Figure 6-13. Energy and TEDI Impacts of VFAR in MURBs (source: 2018 Metrics Report)

6.1.3 Impact of GHG/GHGI Targets – Part 3

A separate detailed data collection report has been developed based the modelling developed for this Metrics report, and is attached as Appendix D, including detailed analysis of each climate zone, Step, and archetype, as well as a summary of assumptions.

Key highlights are reproduced below.

The preliminary proposed approach based on that analysis is to set three target levels for Part 3 buildings:

- Medium: intended to require decarbonization of one major system (space heating or hot water).
- Low: intended to require both major systems to decarbonize, but still allows for high-carbon fuel backup heating, cooking loads, or similar.
- Zero-Carbon Ready: All energy end-uses on a low-carbon fuel.

Each GHG target is set at a level which drives a technology or design choice towards lower carbon fuels.

The targets are set using an intensity metric, similar to the existing TEUI and TEDI Step Code metrics, which scale by floor area. Part 3 buildings vary widely in size, and their energy use generally tracks with size (i.e. there is not a substantial portion of fixed loads that stay the same regardless of size).

The preliminary proposed targets used for analysis are:

Table 6-8. Preliminary Proposed GHGI Targets for Part 3 Buildings

Archetype	Medium	Low	Zero Carbon Ready
MURB	7	3	1.8
Office	5	3	1.5
Retail	6	3	2
Hotel	9	4	2

Initial discussion on targets centered around a 6/3/1 set of targets. This format is generally adhered to, however some changes for individual archetypes have been suggested above to better target the desired level of decarbonization measures, while remaining achievable without requiring renewables such as solar photovoltaics.

First, targets are analyzed based on a simple spreadsheet calculation using the existing Step Code TEUI and TEDI targets, combined with domestic hot water usage modeled in the archetype models. Using these existing targets, and assigning heating and DHW to a high-carbon fuel as an initial baseline (and assuming a 95% condensing boiler for heating), and assuming the rest of the energy use allowable in the TEUI uses a low-carbon fuel, the following GHGI values (in kgCO2e/m^2/year) are seen. This could be considered a "typical worst case" as it uses the maximum allowable TEUI and TEDI for each Step; many projects would be expected to be below those maximums in reality.

The initial targets are set using an allowance based on these maximums, then validated against archetype modelling, described below.

This analysis is summarized below, with levels that would be achieved with each decarbonization measure shown shaded in green.

<u>Target levels</u>

- Each Step and climate zone shows an option to use decarbonization to meet proposed targets at the appropriate decarbonization measures and Steps. In general, targets appear to generate the desired outcomes.
- Ability to meet targets does not appear to depend substantially on climate zone but rather on employing effective use of low-carbon fuels. As such and for simplicity, we have proposed a single set of targets for all climate zones.
- Buildings which fully decarbonize would meet the currently proposed zero carbon ready targets. None would meet the initially proposed target of 1 $kgCO_2e/m^2$/year; significant TEUI savings (up to 50% below Step 2 and nearly 40% below Step 4), or use of

renewable energy generation such as PV or wind power would be required if a target of 1 was set. This generally holds true in archetype modelling though the office archetype does show some high-efficiency options that would meet a GHGI of 1. All other archetypes do not.

- Office archetype modelling showed several instances of designs with high-carbon backup heating falling into the zero carbon ready targets, and was therefore reduced to 1.5 rather than matching other archetypes at a level of 2. Other archetypes may show similar outcomes in some cases but may have difficulty meeting 1.5 in colder climate zones.

Impact of Steps

- This analysis also shows the generalized impact of increasing the Step on decarbonization.
- Targeted decarbonization measures have significantly greater impact on GHG savings, compared with much smaller impact from TEUI/TEDI Steps. When increasing Steps without employing targeted decarbonization measures, the carbon savings range from 12% - 30%. The use of decarbonization measures within the same energy Step is in the range of 76% - 92%.

While moving to a higher energy Step for a particular project may assist in meeting thresholds where they are close, it is not expected to typically be the major driving factor of decarbonization measures selected or the number of decarbonization measures required.

Renewable Natural Gas

Using renewable natural gas (RG or RNG) can lower the carbon emissions of a building compared to conventional natural gas.

This document includes an analysis illustrating the potential blend of renewable gas (RG or RNG) required to achieve the same stepped GHGI targets if all-gas equipment were used.

The annual modelled utility cost of RNG assumes an unlimited supply and is based on rates accurate at the time of publishing.

The archetype examples below focus primarily on electrification decarbonization measures; the energy and cost implications for these measures are more complex and require significant analysis to understand.

Renewable natural gas (RNG) decarbonization measures are much simpler from an analysis perspective:

- Use of RNG does not require changes to natural gas baseline equipment and therefore do not incur incremental capital costs.
- Utility cost of RNG in the analysis ends up cost neutral with natural gas once escalating carbon taxes over a 20-year period are accounted for
- Thus, RNG becomes a simple 1:1 substitution for the modeled base case, which is typically natural gas.
- The main issue considered is therefore what blend of RNG, as a percentage of total natural gas, would be sufficient to meet GHG targets? This is shown below.

The percentage of RNG required to meet targets is shown as a range because it will typically depend on the climate zone, with warmer climate zones requiring a lower percentage and colder climate zones requiring a higher percentage. The percentage required will vary with project specifics and design, for example a design that reduces natural gas heating loads would require a lower percentage of RNG. The below should be considered as a non-exhaustive example only. The below uses Step 2 as a base case.

Table 6-10. RNG as a Percentage of Total Natural Gas Required to Meet Targets

Archetype	% RNG to meet Medium GHG Target	% RNG to meet Low GHG Target	% RNG to meet Zero-Carbon Ready GHG Target
MURB (high and low rise)	50% - 70%	75% - 85%	90% – 95%
Office	50%	75%	95%
Retail	30% - 60%	75% - 85%	90% – 95%
Hotel	60%	85% - 90%	95% - 97%

Archetype Analysis

The tables included in the detailed analysis (included as Appendix D of this report) contain examples of modeled greenhouse gas emissions for a particular archetype, location, and set of design measures. The "base case" within the table uses a high-carbon fuel and approximately Step 2 design measures (envelope, heat recovery) to set an initial baseline prior to decarbonization. Decarbonization measures are then applied to heating and domestic hot water, separately and in combination. This is not an exhaustive list of options to meet targets but is meant to demonstrate a few example points, with key metrics including incremental capital cost, utility cost, and the GHG target level achieved.

Targets Achieved

Each archetype shows at least one fully decarbonized, zero carbon ready option.

- Designs using one decarbonization measure generally meet medium targets, as expected. In some cases a particular measure (either heating or DHW) must be used.
- Designs using high-carbon backup heating fuel, coupled with low-carbon heating system as the primary heating supply, generally achieve the Low target, as expected. There are some cases where they meet either Medium or Zero Carbon ready; these targets fall into a narrow range with some overlap.

Cost Impacts

- Costs for decarbonization remain within 2.5% for all archetypes modelled, to reach Zero Carbon Ready.
- The cost difference between decarbonization measures for climate zone 7a versus 4 is consistently between 0.2% - 0.3% across all archetypes considered. This is further discussed below but suggests a bookending approach to Part 3 decarbonization cost considerations and modelling is appropriate.

Mixed Use Buildings

- Mixed use buildings have not been modeled within these data sheets; it is anticipated that they would follow the procedure outlined in the City of Vancouver Energy Modelling Guidelines

Impact of Steps

A Step 2 base case as well as the impacts of higher Steps are shown for all archetypes. Key observations from this analysis are summarized here.

- Achieving a higher Step will reduce annual heating loads (TEDI) as well as overall energy (TEUI). This leads to carbon reductions, particularly if the heating is supplied by a high-carbon fuel.
- However, efficiency improvements are not a substitute for targeted decarbonization measures. While projects are likely to employ both in combination to some extent, decarbonization measures and targets require over 30% reductions in carbon between levels, and in many cases greater reductions from typical design to even the Medium target. 30% or greater reduction in energy use beyond Step 2 is significant and would require substantial design interventions (this would mean reducing TEUI from Step 2 to somewhat below Step 4 for a MURB.) On the other hand, employing the use of targeted decarbonization measures including RNG and electrification can readily achieve those levels.
- As such, the GHGI-focused archetype analysis focusses on targeted decarbonization measures, including RNG and electrification measures.
- However, significant impacts for a design employing a higher Step would include:
    - Reduced operating costs (via a reduction in load).
    - Potential for reduced equipment size

The full detailed modelling analysis is reproduced as Appendix D to this report. A single example table is shown below to illustrate the available data.

6.1.4 Impact of Overheating Risk Analysis

The individual impacts of passive cooling measures on overheated hours can be considered by varying only one measure at a time, as shown below. The measures are not linearly additive when combined but this isolation method can provide an initial understanding of which measures are likely to have the greatest impact.

Passive and active cooling measures can be combined to allow the design to use passive cooling when conditions are favorable, and supplement with active (mechanical) cooling when required, while employing passive cooling to reduce the mechanical cooling needed. The analysis below considers only passive cooling measures, to analyze overheated hours without active cooling.

The base design case used for the table below uses 2020s weather, mid-performance envelope (described in next paragraph), 40% WWR, SHGC 0.4, 18°C night pre-cool, 0.6m overhang, no bypass or boost, no fins, no exterior operable shading, and 5% of window area being operable. The measures are described in more detail in Section 5.2.

For this overheating analysis, envelope thermal performance and air tightness ECMs were combined into a single measure, described as low-, mid-, and high-performance levels. A low-performance envelope would meet Step 2 for a MURB in climate zone 4 for a VFAR of 0.6. A mid-performance envelope would meet Step 2-3 in climate zone 4. A high-performance envelope for this analysis would meet Step 4 in all climate zones, though naturally all of the Step levels would be dependent on additional factors such as shape, window to wall ratio, HRVs, etc.

The envelope measures were held constant across climate zones to avoid confounding the cost impacts of passive cooling measures being focused on in this targeted analysis with the broader Step requirements addressed elsewhere in the report, while still accounting for some potential difference in cooling measure performance between different envelope performance levels.

The impacts of combining passive cooling measures, as well as cost impacts and options to meet various targets, are explored further below; this initial breakdown is simply to develop an understanding of which individual measures are likely to be the most impactful and the sensitivity to a range of inputs, as well as the impacts of similar measures across different climate zones.

Two sets of results are shown. First, hours overheated based on ASHRAE 55 adaptive comfort model 80% acceptability limits, simplified to use average temperatures of calendar months based on methodology used in the City of Vancouver EMG. The ASHRAE 55 limits vary by location, as someone who has experienced a warmer average temperature recently would be expected to have adapted to be comfortable in somewhat warmer temperatures. This methodology is described in more detail in Section 5.2.

The second set of results simply totals hours where the modeled indoor temperature is over 26°C, and does not vary by location, allowing a more straightforward illustration of hours over a specific and constant threshold.

All overheating results are taken from the worst-case zones in the model from an overheating perspective, determined by examining the maximum number of overheated hours for each zone.

Passive cooling measures and model inputs are described more thoroughly in Section 5.2.

Table 6-11. Single measure impact on overheated hours, with 2020s weather except where noted

Weather Weather files are future-shifted but still "typical weather year" and exclude extreme weather events.	2020s 2050s	573 872	656 1027	1274 1683	1584 1953	564 800	518 759	704 961	659 886	687 900	795 1081	No future weather files available for this location.	

*Fins are modeled relatively conservatively at 6 fins per façade on all facades, spaced widely apart (on average approximately 4m apart); a more optimized design may provide higher impact.

** In some modeled cases night pre-cool has minimal impact as overnight indoor air temperatures stay warmer than 18°C so reducing the setpoint lower has no effect. This measure is expected to be more effective in combination with other measures. Where there are slight differences with lower setpoints leading to 1 hour more this appears to be a rounding difference in the simulation; no actual increase is expected.

It can be seen that the largest individual impacts are from providing significant areas of operable windows including balcony doors, reducing solar heat gains of vision glass, and reduced window to wall ratio.

These measures may have an impact on TEDI, in particular:

- Decreasing solar heat gain coefficient of windows is expected to increase TEDI due to a reduction in available solar heat gains. In some cases SHGC reductions are also tied to improved thermal performance of glazing due to added low-e coatings.
- A wide range of thermal performance options do exist for operable glazing, however operable windows do have lower thermal performance than comparable fixed windows.

The impacts of SHGC on TEDI and TEUI are shown in the main body of the results.

The changes in typical weather years from the 2020s to the 2050s would lead to between a 30% and 60% increase in unmet hours in the base design case, without accounting for either mitigations provided by passive cooling design measures, or increases in unmet hours that may occur due to increased frequency of extreme weather events.

Another point of note is that a significant improvement in envelope thermal performance does increase overheated hours. However, the impact of higher envelope performance is readily compensated for by improving operable windows or other measures. It is possible to both improve envelope thermal performance and reduce overheated hours.

One significant limitation in the effectiveness of operable windows on projects may be the requirement for limiters. Balcony doors tend to provide a much larger open area, however typically other windows on high-rise buildings require and are supplied with limiters which only allow a 100mm opening. Casement or awning windows with a limiter can provide somewhat more open area than a sliding window with a limiter. The impact of limiters on an individual project can vary significantly based on the size of windows, proportion of balcony doors, and type of windows. The model looks at a proportion of total window area that can be opened.

Another significant limitation on many of the passive cooling measures described, including operable windows, night pre-cool, and HRV bypass and boost, is outdoor air temperature. If it is warmer outside than indoors, providing additional outdoor air will not significantly help to cool the space. Night pre-cool is dependent on cooler night-time temperatures, which may not be available in a heat wave.

Heat waves are expected to become more extreme and frequent over time, reducing the effectiveness of these measures at times when they are needed most. Increased frequency and severity of extreme weather is not accounted for in this study.

The tables below show, for all climate zones:

1) The 10 scenarios with the lowest number of overheated hours compared with ASHRAE 55 simplified method based on a 2020s typical weather year, excluding extreme weather events,
   a. holding the envelope fixed at "mid"-level performance and window to wall ratio fixed at 40% for climate zones 4-6 (as these are the most likely to represent a "typical" design), and
   b. holding the envelope fixed at "high"-level performance and window to wall ratio fixed at 20% for climate zones 7a-8 (as these climate zones are likely to require additional ECMs to meet Steps)
2) The 10 lowest incremental capital cost scenarios meeting a 200-hour threshold (the current threshold in the City of Vancouver EMG) with ASHRAE 55 simplified method based on 2020s typical weather year, with envelope and window to wall criteria same as above.

Table 6-12. Passive cooling measures combined impacts – 10 lowest number of hours over simplified ASHRAE 55

8	No scenarios meet 20 hours criteria																	

With the exception of climate zone 5, all other climate zones have a combination of modeled passive cooling options to meet a 200 hour maximum.

Very few of the options modeled (for any range of envelope or WWR inputs) would meet the 20 hour maximum for vulnerable populations, based on future-projected 2020s and 2050s weather. It may be possible to meet the 20-hour target based on CWEC 2016 weather files that are backward-looking and have cooler temperatures; in addition it may be possible to meet this target with project-specific design optimization. However, active cooling or additional design measures that fall beyond the range of the typical measures included in this study would likely be required for most buildings to meet 20 hours for vulnerable populations based on any future-projected weather.

Most projects in climate zone 5 are also unlikely to be able to use only passive cooling measures to achieve a 200 or fewer overheated hours target using future-projected weather files, though project-specific design optimization may certainly be possible leading to improved outcomes compared with a generalized archetype study.

Using the 2050s future projected weather, most climate zones are very close to or slightly over the 200 hour limit even applying the most aggressive combination of passive cooling measures included in the study. Climate zone 5 (using the Kamloops weather file) has more cooling degree days than other climate zones, and has substantial overheated hours using the 2020s weather file. With 2050s weather, the model shows approximately 700 overheated hours, and, if this represented 12 hours per day of overheating, would be approximately two months of overheating per typical weather year (not accounting for extreme weather events such as heat waves).

Climate zone 4 does maintain options to meet a 200-hour target even using future-projected 2050s typical weather year files, with the best case scenarios around 80 hours. Climate zone 6 scenarios approach very close to 200 hours (approx. 195 – 205 for the best cases). The lowest in climate zones 7a and 7b are approximately 250 hours. Future-projected weather files are not available for Yellowknife (climate zone 8).

It should be noted that the ASHRAE 55 acceptability limits have not been adjusted in this study to account for changing comfort criteria as occupants get acclimatized to higher temperatures; the 2020's based limits are applied throughout for a more readable comparison of indoor temperatures.

If mechanical cooling is not required currently, consideration could be given to employing resiliency measures allowing for straightforward future installation of mechanical cooling, such as sufficient electrical infrastructure and planned locations of future cooling systems.

6.1.5 Cost Impacts – Part 3

The cost impacts of the BC Energy Step Code Steps are evaluated using several metrics, and the average of the 10 best scenarios for each metric are summarized below. Each metric is evaluated individually, so for example the lowest incremental capital cost scenario may not have the same design characteristics as the most favorable scenarios for NPV. In reality,

project teams may optimize for any of these characteristics or a combination thereof, or based on other needs entirely, and the outcomes on a project by project basis are expected to vary.

A brief sensitivity analysis of discount rate and carbon tax is shown below.

The individual scenarios summarized in the table below are available as tables in Appendix C.

Lowest ICC

Table 6-15. Average cost impact of 10 lowest ICC Options

	Step	Lowest % ICC Average of 10 Best					
		CZ4	CZ5	CZ6	CZ7a	CZ7b	CZ8
Hotel	1	0.0%	0.1%	0.3%	0.1%	0.2%	-4.4%
	2	0.5%	0.8%	2.0%	2.2%	4.9%	10.6%
	3	1.7%	2.8%	4.4%	4.5%	11.2%	11.4%
	4	N/A	7.3%	9.1%	9.1%	12.1%	N/A
High MURB	1	-0.4%	-0.4%	-0.3%	-0.1%	Not run	Not run
	2	0.0%	0.5%	1.6%	2.9%	Not run	Not run
	3	0.5%	0.9%	5.2%	10.2%	Not run	Not run
	4	3.1%	3.7%	11.8%	12.4%	Not run	Not run
Low MURB	1	-0.4%	-0.4%	-1.2%	-0.1%	-18.9%	0.2%
	2	-0.4%	0.4%	0.5%	0.3%	2.8%	2.1%
	3	0.4%	0.4%	2.8%	3.4%	4.9%	4.3%
	4	1.3%	2.3%	4.6%	5.4%	7.3%	6.8%
Office	1	-1.8%	-2.2%	-2.2%	-1.7%	Not run	Not run
	2	-2.3%	-2.2%	-2.0%	-0.3%	Not run	Not run
	3	-2.3%	-2.0%	-1.2%	0.7%	Not run	Not run
Retail	1	-9.0%	-10.0%	-12.1%	-7.4%	Not run	Not run
	2	-9.1%	-9.3%	-11.8%	-6.4%	Not run	Not run
	3	-8.9%	-9.0%	-10.4%	-5.4%	Not run	Not run

A negative % ICC indicates that there is a potential cost savings available, compared with the NECB 2015 baseline. In general, this is assessed because of differences in window to wall ratio and tradeoffs between window and wall performance. In cases where the window is higher cost than the wall, reducing window area would provide a cost savings, and vice-versa. This is particularly true in the retail archetype, where the proposed scenarios only test 5% to 20% window to wall ratio, a reduction in window area compared with the baseline. Similarly, where

the baseline requires HRVs, a proposed scenario that achieves targets without using HRVs may see a cost savings.

One other element of note is that the hotel in climate zone 4 does not show any options meeting Step 4. This is due to high TEUI in the simulated archetype hotel, which includes commercial kitchen, laundry, and pool loads for all cases. If process loads were reduced, the archetype would readily meet targets.

Near-zero infiltration options have been excluded from most runs, with the exception of some high Steps in cold climate zones. See Section 2.1.3 for discussion. The runs that include near-zero infiltration are: Step 4 hotel in CZ 4-6 and 7b, and Step 3 hotel in CZ8; Step 4 in CZ7a for high-rise MURB, and Step 4 for CZ7a and 7b for low-rise MURB. This applies to both ICC and NPV, below.

Highest NPV

	2	-214,683.5	-96,537.8	-449,277.8	-59,333,086.1	Not run	Not run
	3	-3,419,301.4	-68,405.9	-71,063.8	-1,178,806.5	Not run	Not run

A negative cost of GHG abatement indicates that carbon abatement is actually a cost savings to the project. Larger numbers, such as the retail cost of GHG abatement, are based on scenarios which have a high incremental capital cost savings, but save a fairly small amount of GHG emissions. This leads to a large numerator and small denominator (less than 1 but above 0), and therefore a very large cost savings per tons CO2 saved. These $/tCO2e saved do not necessarily scale across measures that would save larger amounts of GHG emissions. Further discussion of measures that specifically target GHG savings, and the costs thereof, can be found in Section 6.1.3.

Unlike the 2018 Metrics Report, which used NPV $/GHG saved, the table above uses $ ICC / GHG saved. This methodology was used because the NPV was fairly widely varied in both the

previous report and this one, whereas the ICC metric was somewhat more consistent across Steps and locations, allowing greater clarity and simplicity in understanding patterns across the analysis.

NPV Sensitivity

A 3% discount rate is applied to results throughout the study, and the NPV considers a 20-year life. A 2% utility escalation rate is included, and an escalating carbon tax is also accounted for (with separate sensitivity analysis shown below.)

The following example uses the high-rise MURB in climate zone 4 to investigate sensitivity of NPV to discount rate. The same scenario, a Step 3 building with electric baseboards and electric resistance DHW, is used for all scenarios in Tables 6-18 and 6-19 below.

Table 6-18. Discount Rate Sensitivity Analysis

Discount Rate	Utility Cost Escalation Rate	Total ICC ($/m²)	Annual Energy Cost ($/m²/yr average over 20 years in today's dollars)	20-year NPV ($/m²)
2%	2%	20.9	9.6	63.7
3%	2%	20.9	8.8	56.0
4%	2%	20.9	8.1	49.2
5%	2%	20.9	7.4	43.4
6%	2%	20.9	6.9	38.2
7%	2%	20.9	6.4	33.6
8%	2%	20.9	5.9	29.6
9%	2%	20.9	5.5	26.0
10%	2%	20.9	5.2	22.9

Table 6-19. Utility Cost Escalation Rate Sensitivity Analysis

Discount Rate	Utility Cost Escalation Rate	Total ICC ($/m²)	Annual Energy Cost ($/m²/yr average over 20 years in today's dollars)	20-year NPV ($/m²)
3%	1%	20.9	8.0	50.8
3%	2%	20.9	8.8	56.0
3%	3%	20.9	9.6	61.8
3%	4%	20.9	10.6	68.3
3%	5%	20.9	11.6	75.7
3%	6%	20.9	12.8	84.0
3%	7%	20.9	14.2	93.3
3%	8%	20.9	15.7	103.8
3%	9%	20.9	17.4	115.6
3%	10%	20.9	19.3	129.0

A higher discount rate leads to lower NPVs, as future utility cost savings are evaluated as lower worth than with a lower discount rate.

The utility escalation rate also impacts NPV, as greater utility cost savings compared with a base case building lead to improved paybacks.

A brief combined analysis of utility cost escalation and discount rate is shown below. In the base case results of the report, the utility cost escalation rate is 1% below the discount rate (escalation = 2% and discount = 3%). This relationship as well as other potential relationships between the two is tested.

Table 6-20. Utility Cost Escalation Rate and Discount Rate Sensitivity Analysis

Discount Rate	Utility Cost Escalation Rate	Total ICC ($/m²)	Annual Energy Cost ($/m²/yr average over 20 years in today's dollars)	20-year NPV ($/m²)
3%	2%	20.9	8.8	56.0
5%	4%	20.9	8.8	53.0
5%	5%	20.9	9.6	58.7
6%	5%	20.9	8.8	51.8
8%	7%	20.9	8.8	49.9
8%	8%	20.9	9.6	55.5
9%	8%	20.9	8.8	49.1

Carbon Tax Sensitivity

To conduct a brief sensitivity analysis for carbon pricing, the most significant impacts will be seen in GHG reduction measures. The table below summarizes the costs between condensing boiler and ASHP for a high-rise MURB in climate zone 7a. Other design measures are held constant (mid density, VFAR 0.6, wall R-10, roof R-40, code infiltration, window-to-wall ratio 40%, 20% domestic hot water savings).

In all cases, the utility cost for the air-source heat pump building on an annual basis is lower than that of the boiler, though the 20-year NPV of the ASHP is still lower than that of the lower capital cost boiler scenario.

Table 6-21. Sensitivity Analysis for Carbon Pricing for a MURB in CZ7a

Heating System	Carbon Cost Scenario	Annual Utility Cost ($/m²)	GHG Abatement ($/m²)	ICC ($/m²)	NPV
Condensing Boiler	Escalate to 300	13.9	48.1	55.4	-38.3
Condensing Boiler	Stop at 170	13.5	48.1	55.4	-38.8
Condensing Boiler	Stop at 50	12.3	48.1	55.4	-40.2
ASHP	Escalate to 300	12.5	10.1	104.2	-58.3
ASHP	Stop at 170	12.3	10.1	104.2	-63.1
ASHP	Stop at 50	11.7	10.1	104.2	-76.2

6.2 Part 9

6.2.1 Comparison with 2018 Metrics Report

Step Code metrics have changed since the 2018 Metrics Report (e.g. the use of Adjusted TEDI and % better than envelope), and the present report includes some additions and changes to the models (e.g. the inclusion of the laneway dwelling). However, a brief comparison of the lowest-cost ECMs and results for one of the archetypes that was modeled in both reports may provide some context for similarities and differences.

Looking at the medium single family dwelling in climate zones 4 and 7a, the following significant ECMs and ICC comparison can be made. The 2018 Metrics Report scenario is from the lowest ICC table in Section 8.8; the current report scenario is selected to represent a similar set of inputs from the set of lowest ICC results.

Table 6-22. Comparison of Medium Single Family ECMs and results in 2018 and current reports

	Climate Zone 4 (Vancouver)		Climate Zone 7a (Fort St. John)	
	2018 Metrics Report	Current Report	2018 Metrics Report	Current Report
Step 3				
Step 3 Energy Conservation Measures	ACH@50Pa 2.5 Wall R-16 Foundation Wall R-11 Underslab R-11 Ceiling/Roof R-50 Window USI-1.6 DHW: Electric Storage Heating System: Baseboard HRV 60% Drainwater heat recovery: none	ACH@50Pa 2.5 Wall R-22 Foundation Wall R-17 Underslab R-11 Ceiling/Roof R-60 Window USI-1.8 DHW: Tankless gas Heating System: gas furnace HRV: none Drainwater heat recovery: 30%	ACH@50Pa 1.5 Wall R-16 Foundation Wall R-17 Underslab R-0 Ceiling/Roof R-40 Window USI-1.2 DHW: Baseline Heating System: Baseboard HRV: 60%	ACH@50Pa 1.5 Wall R-22 Foundation Wall R-17 Underslab R-11 Ceiling/Roof R-50 Window USI-1.4, SHGC 0.35 DHW: Baseline Heating System: gas furnace HRV: None

Step 3 Incremental Capital Cost	0.9%	1.1%	0.8%	1.2%
Step 5				
Step 5 Energy Conservation Measures	ACH@50Pa 0.6 Wall R-24 Foundation Wall R-20 Underslab R-11 Ceiling/Roof R-40 Window USI-1.2 DHW: Heat Pump Heating System: Baseboard HRV 70% Drainwater heat recovery: none	ACH@50Pa 1.o Wall R-30 Foundation Wall R-17 Underslab R-10 Ceiling/Roof R-60 Window USI-1.4 DHW: Tankless gas Heating System: ASHP HRV: 60% Drainwater heat recovery: none	ACH@50Pa 0.6 Wall R-40 Foundation Wall R-17 Underslab R-0 Ceiling/Roof R-70 Window USI-1.2 DHW: Instant Gas Heating System: Baseboard HRV: 70%	ACH@50Pa 0.6 Wall R-30 Foundation Wall R-17 Underslab R-14 Ceiling/Roof R-60 Window USI-1.4 DHW gas Heating System: CCASHP HRV 75%
Step 5 Energy Results (all in kWh/m²/year)	MEUI 23 TEDI 14	MEUI 25.6 TEDI 17	MEUI 54 TEDI 31	MEUI 59 TEDI 45.9
Step 5 Incremental Capital Cost	3.6%	2.9%	3.4%	3.1%

The Step 3 results in climate zone 4 in the current report show higher insulation values , and generally include either reduced air leakage to 1.5 ACH or drainwater heat recovery (a drainwater heat recovery scenario is shown in the table above), whereas the 2018 report shows somewhat lower envelope efficiency but includes an HRV as its lowest cost scenario. The incremental capital costs are very similar, with a slight increase in the current report.

Similarly, the lowest cost Step 3 results in climate zone 7a in the current report have improved envelope compared with the 2018 report but no HRV. The incremental capital cost percentages are the same between the 2018 results and current results. The MEUI and TEDI are higher in the current report, while still meeting Step 3. The TEDI can be higher while still meeting the Step 3 target TEDI due to the adjusted TEDI process, and the MEUI can be higher since the current report ECM package includes a CCASHP which means the calculated MEUI was compared to the MEUI target for houses with cooling.

Step 5 scenarios in the current results have slightly lower incremental costs compared with the 2018 report, and have more variation between solutions. One observation is that the solutions considered in the 2018 report used electric baseboards, while the lowest incremental capital cost solutions used for Step 5 in the current results set more typically use heat pumps; this may allow added flexibility in other measures such as envelope that result in lower overall ICC while still meeting targets.

Overall, within the locations and Steps examined above, similar ICCs are maintained from the 2018 Metrics Report to the current results set.

6.2.2 Impact of Shape and Window Area Variations

The medium and large single family dwellings were run with varied window to wall ratios (WWRs) and with varied building surface area to floor area ratio (SAR). The base case medium and large SFDs have window to wall ratios of 13%, increased by increments of 5% to 18% and 23%. The SAR for both medium and large SFDs is increased by 25% and by 50% from the initial base case model.

Additional window area drives a requirement for additional energy conservation measures to maintain energy performance. However, at lower steps and in warmer climate zones the incremental capital cost difference is minimal, at less than 0.3% additional cost. In colder climate zones at higher steps, there is a minor impact going from 13% to 18% window to wall ratio, then a more significant impact increasing further to 23%. This non-linear relationship where the energy impacts are minor within a range of window to wall ratios, then increase significantly above a certain threshold, aligns with the

> Many of the factors impacting SAR are design choices, however some may be required by some jurisdictions, such as a certain amount of articulation. Jurisdictions adopting the BC Energy Step Code should examine their other policies for alignment with these goals.

authors' anecdotal experience on previous projects. A design choice to increase window area substantially may increase costs for a particular project, requiring additional energy conservation measures to maintain energy performance.

Table 6-23. Impact of Window to Wall Ratio on Incremental Capital Cost

	Climate Zone 4 (Vancouver)			Climate Zone 7a (Fort St. John)		
	13% WWR	18% WWR	23% WWR	13% WWR	18% WWR	23% WWR
Step 3 ICC*	1.2%	1.2%	1.4%	1.3%	1.3%	1.4%
Step 5 ICC*	2.9%	3.0%	3.2%	3.1%	3.3%	4.7%

*Average of approximately 10 lowest ICC results.

The building surface area to floor area ratio, or SAR, is a means of quantifying the shape of the building, looking at the amount of exterior surface area (e.g. walls, roofs) compared with the amount of floor area. Higher SAR indicates more exterior surface area, therefore more heat loss via the exterior surfaces. Higher SAR may be indicative of shape complexity or articulation, a narrower floor plate, or higher floor-to-floor heights. It is anticipated that if SAR increases, additional energy conservation measures would be required to maintain energy performance. As the SAR increases, the window to wall ratio is maintained at the same percentage, thereby adding more absolute window area in proportion with the additional wall area. The SAR was increased in the model by adding length to the walls, while retaining the house floor area and volume as per the original model.

Table 6-24. Impact of Surface Area Ratio on Incremental Capital Cost

	Climate Zone 4 (Vancouver)			Climate Zone 7a (Fort St. John)		
	Base Case SAR	25% Increase	50% Increase	Base Case SAR	25% Increase	50% Increase
Step 3 ICC*	1.2%	2.0%	2.5%	1.3%	2.2%	2.5%
Step 5 ICC*	2.9%	3.9%	5.0%	3.1%	5.3%	6.5%

*Average of approximately 10 lowest ICC results.

The increase in energy conservation measures and associated costs to maintain performance if SAR increases are significant, and appear relatively consistent across the range of SARs tested. Many of the factors impacting SAR, noted above, are design choices, however some may be required by some jurisdictions (e.g. a certain amount of articulation), or may be dictated by site constraints (e.g. a narrower floor plate). Jurisdictions adopting the BC Energy Step Code should examine their other policies for alignment with these goals.

6.2.3 Impact of Laneway Home

The new laneway or smaller single family home model was created for this report and was not included in the previous 2018 Metrics Report. The laneway home is 750 ft^2, compared with 1100 ft^2 for the small single family dwelling, and is 2 storeys slab on grade.

Comparing with the medium single family dwelling to provide context, we can consider Step 3 and Step 5 runs in climate zones 4 and 7a, and consider the ECMs needed as well as the incremental capital costs. The table directly below compares sets of ECMs that are among the lowest ICC options for each dwelling type within the relevant Step.

Table 6-25. Laneway House and Medium SFD Measure Comparison – Low ICC Options

	Climate Zone 4 (Vancouver)		Climate Zone 7a (Fort St. John)

Wall	R-40	R-30	R-40	R-40
Slab on Grade	R-14	R-10	R-10	R-10
Heating	Electric Baseboard	ASHP	CCASHP	CCASHP
HRV	85%	60%	75%	75%
DHW	HP	Tankless Gas	Tankless Gas	Gas
ICC ($) with CZ multiplier	10,520	14,903	23,762	23,672
ICC (%)	5.3%	2.9%	8.0%	3.0%
TEDI	17.8	17.4	51	45.1
MEUI	54.3	25.7	102.4	58.8
GHGI	1.7	3.4	13.2	6.4
% better than ERS	21.9%	37.7%	36.7%	45.9%
% better than Envelope	33.8%	40.2%	52.4%	43.7%

In all cases, the MEUI of the smaller laneway house is significantly higher. This is as expected; a smaller home will have many of the same loads (e.g. showering, dishwashing) spread out over less area. Energy modelling protocols for Step Code compliance follow EnerGuide Rating System standards, which assume the same occupants, hot water consumption and lighting/appliance/plug loads regardless of the size of the house. This is accounted for within the BC Energy Step Code by adjusting the targets to account for this.

The % ICC at Step 3 is relatively close between the laneway home and medium single family home, with approximately a 1% increase for the laneway home. The absolute value of the incremental capital cost is lower at Step 3 for the laneway home, however the laneway home's base construction cost is estimated lower than the medium single family dwelling, such that the denominator of the percentage calculation is impacted, and the ECMs become a larger proportion of the estimated total build cost.

At Step 5 in a warmer climate, a similar result holds true, with lower absolute incremental capital cost for the laneway home, but with a greater differential of % ICC and a relatively high ICC percentage, which may be of concern. For Step 5 in a colder climate, the absolute incremental cost value of ECMS in the laneway home is nearly equal to that of the medium single family home (within 1%), and continues to have a high % ICC.

The above results show a comparison among the lowest ICC options. However, they do not make it clear whether, or to what extent, the laneway homes require increased levels of ECMs, or whether the impacts on costs are primarily related to the lower total base case cost of the laneway homes due to their smaller size (for example, countertops or appliances also cost "more" in a small home – as in, they cost a larger percentage of the total budget, since the total cost is smaller).

To evaluate the necessity of more stringent ECMs, an additional set of scenarios is considered in Table 6-21, where the medium single family ECMs noted in the table above are applied to the laneway home, and the resulting Step level for the laneway home is checked. If the same set of options meets the same Step in the laneway home, that would tend to indicate that similar ECMs would meet similar Steps, whereas if additional ECMs are required, it may be indicative of inequity towards smaller homes.

The laneway home uses electric baseboard as the "base case" heating system, whereas the medium single family home uses gas furnace.

Table 6-26. Laneway House and Medium SFD Measure Comparison – Same ECMs

	Climate Zone 4 (Vancouver)		Climate Zone 7a (Fort St. John)

Step Level	4	5	4	5
ICC ($)	11,389	14,903	18,275	24,003
ICC (%)	5.7%	2.9%	6.1%	3.0%
TEDI	17.7	17.4	51.6	45.1
MEUI	71.5	25.7	60.9	58.8
% better than ERS	19.2%	37.7%	52.1%	45.9%
% better than Envelope	35.3%	40.2%	53.2%	43.7%

The table above demonstrates that overall, the laneway home does require additional energy conservation measures compared with the medium single family dwelling to achieve the same Step levels.

6.2.4 Impact of Part 9 GHG/GHGI Targets

Similar to the data sheets developed for Part 3, a separate detailed GHG analysis was developed for Part 9 using the modelling developed for this report. The full detailed analysis is included as Appendix D.

Key highlights of the analysis are reproduced here.

Three levels of GHG Target are set, with the intent of driving decarbonization design measures at each level.

- Medium: The larger of either heating or DHW must use a low-carbon fuel.
- Low: Allows for smaller end uses such as cooking or gas dryers to use high-carbon fuel, or allows use of a small portion of high carbon fuel for large end uses (e.g. backup heating) but requires low-carbon fuel for most end-uses.
- Zero-Carbon Ready: All energy end-uses on a low-carbon fuel.

The targets proposed within this report are preliminary for consideration and analysis.

Building Size

Building size is accounted for by setting an absolute base allowance and a maximum cap per unit for all buildings, then scaling the GHG targets linearly by size of dwelling between the base allowance and maximum cap for each level. The unit base allowance was set for 175 m^2 dwelling unit, the maximum cap based on a 400 m^2 dwelling unit.

The targets would be scaled by number of dwelling units in the building; e.g. a 4-plex would have four times the base per-unit allowance.

The reasoning for this approach is that:

- The base allowance per unit allows for fixed loads, such as domestic hot water or plug loads, that do not depend on the size of the dwelling. This assists modelling, design and construction of small, affordable housing units, while having minimal GHG impacts.
- The maximum cap per unit reflects that it is easier to achieve GHGI reductions in larger buildings.
- The GHGI variation between the minimum and maximum targets is used to drive efficient low-carbon building and mechanical design.

Targets are set using current Step 3 MEUI and TEDI targets, as well as an additional allowance for plug loads, lighting, and other base electric loads. This means each GHGI target is designed to be realistic for a Step 3 home to achieve when it decarbonizes one or more systems such as domestic hot water or heating. This also means that each GHGI target should, in theory, be even easier to achieve if a home meets Steps 4 or 5.

Climate Zones

The same targets are used for all climate zones; this reduces complexity and appears to be achievable based on the analysis conducted. The use of fuel switching causes significant reductions regardless of loads. Break points remain between target levels that generally encourage decarbonization at the appropriate levels. However, this can make more stringent targets in colder climate zones more challenging and introduce cost differentials.

Modelling Guidelines

Modelling guidelines may be required to ensure alignment between projects, including:

- GHG emission factors.
- Modelling auxiliary loads such as cooking loads, fireplaces, dryers, etc. using the appropriate fuels.
- Modelling backup heating appropriately.

Prescriptive Option

In addition, the potential for a prescriptive compliance path option is considered. Prescriptive target requirements are aligned with the intent of how the modeled targets were set.

The draft Medium target proposes to require heating to be decarbonized regardless of whether heating or domestic hot water would be more impactful for a particular building. Heating would be more impactful for buildings with higher absolute GHG use, in particular larger homes as well as those in colder climates. Therefore, for the backstop prescriptive target, the larger total impact measure across all dwellings is proposed as the requirement.

Table 6-27. Preliminary Proposed Part 9 Targets

	All Buildings: GHG Base Allowance per unit	OR	The smaller of GHG intensity or the maximum absolute cap, for the unit size.		OR	Prescriptive option (under consideration)
			Building GHG Intensity	GHG Maximum Cap per unit		
	kg CO2e per unit		kgCO2e/m2/year	kg CO2e per unit		
Medium	1050		6	2400		Decarbonize heating.
Low	440		2.5	800		Only backup heating or auxiliary uses (cooking, fireplaces, etc.) are allowed to use high carbon fuel.
Zero Carbon Ready	265		1.5	500		Project is fully decarbonized.

Renewable Natural Gas Analysis

Using renewable natural gas (RG or RNG) can lower the carbon emissions of a building compared to conventional natural gas.

The archetype examples focus primarily on electrification decarbonization measures because the energy and cost implications for these measures are more complex and require significant analysis to understand.

Renewable natural gas (RNG) decarbonization measures are much simpler from an analysis perspective:

- Use of RNG does not require changes to natural gas baseline equipment and therefore do not incur incremental capital costs.
- Utility cost of RNG in our analysis ends up cost neutral with natural gas once escalating carbon taxes over a 20-year period are accounted for (see assumptions above for more detail.)
- Thus, RNG becomes a simple 1:1 substitution for the modeled base case, which is typically natural gas.
- Therefore, what blend of RNG, as a percentage of total natural gas, would be sufficient to meet GHG targets?

The percentage of RNG required to meet targets is shown as a range because it will depend on the size of the dwelling (50 m^2 to 225 m^2 is shown below), with smaller homes requiring less RNG to meet targets. The percentage required will also vary with project specifics and design, for example a design that reduces natural gas heating loads would require a lower percentage of RNG. the below should be considered as a non-exhaustive example only. The below uses Step 3 as a base case

Table 6-28. RNG as a Percentage of Total Natural Gas Required to Meet Targets

Climate Zone	% RNG to meet Medium GHG Target	% RNG to meet Low GHG Target	% RNG to meet Zero Carbon Ready GHG Target
4	15% - 50%	70% - 80%	85% - 90%
5	20% - 80%	60% - 90%	70% - 90%
6	30% - 80%	65% - 90%	75% - 95%
7a	35% - 70%	75% - 90%	90% - 95%
7b	45% - 75%	80% - 90%	90% - 95%
8	50% - 80%	80% - 90%	90% - 95%

Archetype Analysis

The tables included in the detailed analysis (Appendix D) contain examples of modeled greenhouse gas emissions for a particular archetype, location, and set of design measures.

The "base case" within the table uses a high-carbon fuel and varied initial Step level design measures (envelope, heat recovery) to set an initial baseline prior to decarbonization. Decarbonization measures are then applied to heating and domestic hot water, separately and in combination. This is not an exhaustive list of options to meet targets but is meant to demonstrate a few example points, with key metrics including incremental capital cost, utility cost, and the GHG target level achieved. It should be noted that drainwater heat recovery has been excluded from all options for consistency and comparability of results between different Steps but could certainly be applied on projects to reduce domestic hot water load and associated GHGs. In some cases, slightly different measures are provided at different Step levels due to available modelling runs from the Metrics Research Report modelling done.

Levels achieved are determined based on the allowance, GHGI, and maximum cap.

Targets Achieved

- Each archetype in each climate zone shows at least one fully decarbonized, Zero Carbon Ready option.
- Each archetype shows at least one mid-range option, which will typically comply with the Medium target.
- Not all decarbonization measures have the same impact for each archetype and climate zone. Decarbonizing only the smaller of the two typically high-carbon end uses may not be sufficient. In many cases the higher impact of space heating or hot water will need to be decarbonized to meet targets.

- Most archetypes below achieve either no target, Medium, or Zero Carbon Ready. Only a few achieve the Low target. This is because the Low target is set to still require major systems to be decarbonized, but to allow some buffer for smaller end uses such as cooking, gas dryers, or some amount of backup heating. The archetypes modeled use electricity for these end uses by default and use cold climate heat pumps in climate zones 6 and above.

Carbon reduction impacts

A few examples of the amount of carbon reduction are below:

- Laneway home in Vancouver: **89% reduction** from Step 3 base case to Step 3 fully decarbonized.
- Large single family dwelling in Summerland: **95% reduction** from Step 3 base case to Step 3 fully decarbonized.
- Quadplex in Fort St. John: **93% reduction** from Step 3 base case to Step 3 fully decarbonized.
- Medium single family dwelling in Cranbrook: **70% reduction** from Step 3 base case to Step 3 Middle target.
- 10-unit MURB in Fort Nelson: **76% reduction** from Step 3 base case to Step 3 Middle target.

Cost Impacts

- Maximum incremental capital cost for any of the below examples in all climate zones, including zero-carbon ready targets, is 3.4%. Typical incremental capital cost for most archetypes is lower, generally below 1.5%.
- Utility costs typically range from approximately 25% savings to 30% increase in costs related to decarbonization, accounting for increases in carbon taxes over time. There is not a linear relationship between decarbonization and utility costs; with efficiency improvements as well as increasing carbon taxes there are a range of utility cost outcomes shown.
- Utility cost impacts tend to show:
    - Greatest increase when employing electric resistance space heating (which is less efficient than a heat pump)
    - Greatest decrease when using heat pumps for both space heating and hot water

Electric Resistance Heating

In general, heat pumps are used as a decarbonization measure for both heating and domestic hot water. There are a few examples that demonstrate the difference between electric resistance systems (such as electric baseboard) and heat pump for space heating. While electric resistance is less efficient, it can be applied as a decarbonization measure. Electric resistance would typically have lower incremental cost and higher energy cost, and similar but slightly poorer GHG outcomes. The difference in GHG outcomes is likely to be

negligible to most projects and electric resistance could be applied; in particular cases where a design is right at the edge of a target it may not be useable. The same principles apply to using electric resistance for DHW.

Low Target and Backup Heating

The "low" target is intended to allow for some backup or auxiliary high-carbon fuel use but for all major systems to be decarbonized. The modelling done for the Metrics Research Report Update used the low-carbon default fuels for auxiliary uses such as cooking, dryers, etc. Heat pumps modeled for the archetype buildings are cold climate air source heat pumps in climate zones 6 and above, and use electric resistance backup/supplemental heating where required.

The amount of backup high-carbon fuel allowed for (with the rest of the building fully decarbonized) is equivalent to approximately:

- For a large single family dwelling in Fort St. John (climate zone 7a)
    - 12% of Step 3 total annual heating load
    - 15% of Step 5 total annual heating load
- For a quadplex in Fort St. John (climate zone 7a)
    - 30% of a Step 4 total annual heating load
- For a large single family dwelling in Uranium City (climate zone 8)
    - Only allows for 3% of Step 3 total annual heating load.

These projects would likely use the prescriptive option to meet targets. Compliance is also possible if the project fully decarbonizes and does not use high-carbon backup fuel

Detailed Modelling Analysis

The full detailed modelling analysis is reproduced as Appendix D to this report. A single example table is shown below to illustrate the available data.

	5	1.4%	1.5%	1.4%	1.3%	1.5%	1.6%

*Where "-" is shown, none of the simulated options meet the targets.

The average incremental costs compared with the baseline construction cost range from below 1% up to approximately 10%, though generally remaining below 3-4% for most archetypes. The smaller homes (laneway and small SFD) have higher incremental capital costs on a percentage basis, which is as expected as certain measures, such as HRVs, drainwater heat recovery, and to some extent windows and walls, are not dependent or not linearly dependent on floor area, meaning the cost does not change linearly with floor area, whereas the base cost of construction estimate, in this report, does scale with floor area. The absolute costs of ECMs to achieve the same steps in these smaller dwellings remain smaller than the absolute costs to achieve them in larger dwellings (this is as expected; some ECMs such as envelope are expected to cost more in larger homes as there is simply more of it.)

Colder climate zones tend to have somewhat higher costs than warmer climate zones. These dwellings would also be expected to gain the most benefit from reduced heating energy use, assisting with improved NPV. The differences in incremental capital cost tend to increase relatively consistently across different archetypes and steps, without significant jumps for the most part. One exception to this is noted in the laneway homes in climate zone 7b versus 8, where climate zone 7b increases in cost and 8 drops. This is due to more ECMs being required in the base case in climate zone 8, so that the minimum construction requirement is higher and the incremental capital cost beyond minimum is reduced.

Compared with similar results in the 2018 Metrics Report, which looked at the lowest first costs as a % change (Table 30 of the 2018 Metrics Report), results appear to generally have reasonably good consistency, within approximately 1% or closer for most individual data points. While there are a few exceptions, such as lower costs in the 2021 results for the Step 5 Quadplex, there does not appear to be a consistent trend or pattern where there are variations (for example based on climate zone or dwelling size.) The overall average of results is within 0.05% of the 2018 Metrics report % ICC, though with variation both above and below for individual data points.

Data showing the averages of the 10 highest NPV and 10 lowest ICC $/GHG abatement cost options are below.

Highest NPV

As with the Part 3 buildings, the table above uses $ ICC / GHG saved. This methodology was used because the NPV was fairly widely varied in both the previous report and this one, whereas the ICC metric was somewhat more consistent across Steps and locations, allowing greater clarity and simplicity in understanding patterns across the analysis.

7 Summary and Recommendations

7.1 Impact of NECB 2020

In updating to NECB 2020 from NECB 2015 as the base code, the base code becomes more efficient, with average energy performance increases of 12% for retail, 11% for hotel, 33% for office, and 15% for MURB.

The goal is for the new minimum target to require better performance than NECB 2020; and in addition, for performance to be at least 20% better than the 2018 BCBC.

Table 7-1. Recommendations for Updated BC Energy Step Code Targets – Part 3

Archetype	Recommendation for New Minimum Step
MURB (high- and low-rise)	Step 2
Office	Step 2
Retail	Step 2
Hotel	Step 2

This suggested approach recommends an incremental increase in the minimum Step for all archetypes, which aligns with previous messaging and industry perception, as well as making allowance for the significant variation in measures required based on elements such as building shape, program variation, etc.

Both TEDI and TEUI are considered in comparing against NECB to make recommendations; GHGI targets are preliminary as of this report and are not considered. NECB would consider only TEUI for compliance, however TEDI is a significant metric in the BC Energy Step Code and has been considered within the comparison.

Step 2 would beat either the TEDI or TEUI of NECB 2020 for all archetypes modeled, on average across all climate zones. In order to meet the TEUI, a slight increase in stringency of the TEUI target was needed for office and retail.

Step 2 would also show more than 20% savings for either TEDI or TEUI of NECB 2015 (BCBC 2018), with the exception of the retail archetype, which shows 19% savings. The difference between 19% and 20% is well within the margin of error of the nature of an archetype modelling study of this sort and is not expected to be a significant reason to increase the minimum Step for this archetype beyond Step 2.

7.2 GHG/GHGI Targets

The achievability of specific GHG or GHGI targets will depend significantly on the choice of emissions factors to be used in modelling. The City of Vancouver Modelling Guidelines v2.0 emissions factors are used throughout this report.

A further complication is the Fort Nelson grid and local isolated grids, where low-GHG power may not be available. In those areas, it may be necessary to look at future greening of the grid, additional local renewable supply, or a focus on alternative energy sources in order to achieve

deep greenhouse gas emission reductions. For code compliance, the simplest solution may be to have static emission factors for the entire province.

The following targets are initially proposed, targeting 3 levels of GHG reduction and with the intent of driving decarbonization measures at each level.

- Medium: intended to require decarbonization of one major system (space heating or hot water).
- Low: intended to require both major systems to decarbonize, but still allows for high-carbon fuel backup heating, cooking loads, or similar.
- Zero-Carbon Ready: All energy end-uses on a low-carbon fuel.

Table 7-2. Preliminary Proposed GHGI Targets for Part 3 Buildings

Archetype	Medium	Low	Zero Carbon Ready
MURB	7	3	1.8
Office	5	3	1.5
Retail	6	3	2
Hotel	9	4	2

Feasible design measures and cost impacts of these targets are analyzed in detail; the incremental capital cost of decarbonization measures compared against that Step's base case remains below 2.5% for all archetypes.

7.3 Overheating Risk

With the exception of climate zone 5, all other climate zones have a combination of modeled passive cooling options to meet a 200 hour maximum, (considered as an initial target for analysis based on the City of Vancouver Energy Modelling Guidelines v2).

Very few of the options modeled (for any range of envelope or WWR inputs) would meet a 20 hour maximum for vulnerable populations, based on future-projected 2020s and 2050s weather. It may be possible to meet the 20-hour target based on CWEC 2016 weather files that are backward-looking and have cooler temperatures; in addition it may be possible to meet this target with project-specific design optimization. However, active cooling or additional design measures that fall beyond the range of the typical measures included in this study would likely be required for most buildings to meet 20 hours for vulnerable populations based on any future-projected weather.

Most projects in climate zone 5 are also unlikely to be able to use only passive cooling measures to achieve a 200 or fewer overheated hours target using future-projected weather files, though project-specific design optimization may certainly be possible leading to improved outcomes compared with a generalized archetype study.

In addition, as the climate warms, these targets become more challenging to meet, with most climate zones not able to meet a 200 hour maximum based on 2050s weather. While the

evaluation was done using 2020s comfort criteria to evaluate overheating limits, and limits were not changed to account for occupant comfort at somewhat increased temperatures based on acclimatizing to more warmth, this is nevertheless indicative of significant warming, with projects in climate zone 5 potentially encountering in the range of 700 overheated hours during a typical weather year (approximately 2 months' worth of 12-hour days).

A secondary metric was also reported within the analysis, hours over 26°C. This allows for a more fixed comparison of hours between climate zones and over time.

In addition to passive cooling measures, partial or full mechanical cooling may be required to maintain occupant comfort, particularly during extreme weather and smoke events that are increasing in frequency. During extreme heat waves such as those seen across much of BC recently, as well as during periods of poor air quality due to forest fires, one of the most effective passive cooling measures, operable windows, is much less useful or not viable. While passive cooling measures do help to mitigate the impacts of such events, and reduce the risk to occupants in the event of mechanical cooling or power failure, passive cooling by itself will no longer be sufficient to provide for adequate occupant comfort and safety. Both passive and active strategies should be encouraged in combination.

7.4 Part 9

The addition of a smaller/laneway archetype highlighted the increased ECMs that are required for smaller buildings, as well as the higher incremental capital cost on a percentage of base construction cost. However, it should be noted that the absolute costs of ECMs remain lower on an absolute cost basis than those for larger homes.

Analysis of shape factors and window to wall ratios showed significant impacts on the ECMs required as well as the costs of compliance (in both absolute and percentage increase terms) as the surface to floor area ratio or window to wall ratio increase. In general, a 50% increase in SAR was seen to approximately double the incremental cost of compliance. A 5% increase or decrease in window to wall ratio had a much smaller impact on incremental capital cost, in the range of 0.2-0.3%, except for the highest step in the coldest climate zones, which had over 1% incremental capital cost impact. This analysis may be useful for design teams in considering design decisions such as ceiling heights, articulation, and window area, as well as helping to inform local jurisdictions, who may wish to examine their other policies for alignment with these goals.

Three levels of GHG Target are proposed for Part 9 buildings, with the intent of driving decarbonization design measures at each level.

- Medium: The larger of either heating or DHW must use a low-carbon fuel.
- Low: Allows for smaller end uses such as cooking or gas dryers to use high-carbon fuel, or allows use of a small portion of high carbon fuel for large end uses (e.g. backup heating) but requires low-carbon fuel for most end-uses.
- Zero-Carbon Ready: All energy end-uses on a low-carbon fuel.

A per-unit base allowance as well as a per-unit maximum cap are considered, with targets scaling by unit floor area in between. A prescriptive option is also proposed, aligned with the decarbonization measures intent for modeled targets.

The current draft proposed targets used for analysis are as follows:

	All Buildings: GHG Base Allowance per unit	OR	The smaller of GHG intensity or the maximum absolute cap, for the unit size.		OR	Prescriptive option (under consideration)
			Building GHG Intensity	GHG Maximum Cap per unit		
	kg CO2e per unit		kgCO2e/m2/year	kg CO2e per unit		
Medium	1050		6	2400		Decarbonize heating.
Low	440		2.5	800		Only backup heating or auxiliary uses (cooking, fireplaces, etc.) are allowed to use high carbon fuel.
Zero Carbon Ready	265		1.5	500		Project is fully decarbonized.

There are a number of end uses, such as supplemental space heating fireplaces as well as exterior uses, that would be excluded from the models under EnerGuide Rating System protocols; and the fuel source and carbon content of appliances such as cooktops and dryers may not be consistently accounted for in common practice. These could impact GHGI compliance. The potential use of specific modelling guidelines or additional prescriptive requirements could be considered.

Finally, the incremental capital costs are summarized for each Step and archetype across all climate zones. The average incremental costs compared with the baseline construction cost range from below 1% up to approximately 10%, though generally remaining below 3-4% for most archetypes. The values are within similar ranges to the 2018 Metrics Report, and tend to increase as Steps increase, as expected. They also increase for colder climate zones. The percentage increases are higher for smaller dwellings, though the absolute increases are smaller.

	Proposed Design	**NECB 2015 Baseline (BCBC 2018)**	**NECB 2020 Baseline**
Night cycle control	N/A, all operates 24/7		
Outdoor air flow rates	ASHRAE 62.1-2016 2.5 L/s/person + 0.3 L/s/ m^2 (note: model input varies by suite density; number of people varies; combined OA rate varies between approx. 0.36 L/s/ $m^2$and 0.4 L/s/ m^2) Corridor: 0.3 L/s/ m^2		
Parkade	4h/day Exhaust fans 0.5 W/cfm 0.75 cfm/sf exhaust		
DHW			
DHW Load	20% savings (low flow fixtures)	No savings (see internal loads)	
DHW Heating Equipment	Nat gas: 95% Elec resistance	Nat gas: 80% Elec resistance	Nat gas: 90% Elec resistance

Low Rise MURB			
	Proposed Design	**NECB 2015 Baseline (BCBC 2018)**	**NECB 2020 Baseline**
Climate Zone	Climate Zone 4, 5, 6, 7a, 7b, 8		
Weather File	Vancouver Airport CWEC 2016, Kamloops AP CWEC 2016, Prince George Intl AP CWEC 2016, Fort St. John – North Peace Rgnl AP CWEC 2016, Fort Nelson – Northern Rockies Rgnl AP CWEC 2016, Yellowknife AP CWEC 2016		
Software	EnergyPlus v9.4		
Building Area	Same space proportions as high-rise MURB; scaled down for reduced # storeys Uses same model as high-rise; results are per floor area. Costing is different as systems are likely to be constructed differently, e.g. wood frame vs. non-combustible. Climate zones 7b and 8 added to the analysis for low-rise.		
Storeys			
Building Description (space types)			
Visual			
Zoning	Suites exterior, corridor/core interior. Several suites along each façade are combined, which allows variations in suite size within the model (each façade modeled as separate zone to account for variations in load). Zone multipliers used for intermediate floors.		
Internal Loads and Schedules			
Internal Loads and Schedules	See high rise MURB		

Low Rise MURB			
	Proposed Design	**NECB 2015 Baseline (BCBC 2018)**	**NECB 2020 Baseline**
Envelope			
Walls	Varies: R-4, 7, 10, 20, 40	De-rated by 25% to allow for thermal bridging. (Less de-rating than for high rise/non-combustible construction to allow for wood framed construction). Where substantial IT process loads are added; they are added individually to a single dedicated smaller zone rather than distributed throughout. Zone multipliers are used for intermediate floors.

Significant impacts of reduced variability between different spaces are mitigated by accounting for a typical office ventilation effectiveness in a mixed air system when modelling VAV (0.56 used), and by using temperature-first rather than airflow-first controls for the VAV system, which means if large interior zone requires cooling, the system temperature will drop for the whole system, increasing reheat requirements for the system but not massively increasing fan power to meet loads for a single zone.</td></tr>

Roof

$5/inch (R-5) of additional insulation beyond NECB 2015 minimum, plus 2% inflation per year over 3 years
e.g. $23.3/m2 premium for R-20 additional insulation beyond NECB 2015 minimum
Source: 2018 Metrics Report, plus inflation

Windows

Window USI	Description	Cost ($/m² of window area)
Varies	NECB 2015	Varies
Varies	NECB 2020	Varies
2.5	Double glazed aluminum, low-e	970
2	Double glazed aluminum, low-e	1020

	1.6	Higher performance window wall double glazed aluminum, low-e	1130
	1.2	Curtain wall double glazed aluminum, low-e	1290
	0.8	Passive house style. 20% allowance added for structural.	1660

Baseline window performance:

CZ	NECB 2015 USI	NECB 2020 USI	NECB 2015 $/m²	NECB 2020 $/m²	Baseline WWR
4	2.4	1.9	970	1020	0.40
5	2.2	1.9	970	1020	0.40
6	2.2	1.73	970	1130	0.35
7a	2.2	1.73	970	1130	0.28
7b	2.2	1.44	970	1290	0.22
8	1.6	1.44	1130	1290	0.20

Solar heat gain coefficient is assigned no cost premium, as the baseline would be adjusted to match the proposed SHGC. The difference between different low-e coatings is anticipated to be approximately $8/m² ($0.75/ft²) at a maximum, which would have a very small impact on overall cost premiums. Source: Local window supplier and passive house window supplier, checked against consultants and 2018 Metrics Report. For passive house style glazing/triple glazing, added a 20% allowance for structural improvements.

Window to wall ratio

Window and wall incremental costs are calculated against the NECB 2015 baseline window to wall ratio by climate zone.
This may lead to an increase or savings in costs; and would cause cost differentials between climate zones beyond the climate zone multiplier noted below. For instance, for a proposed scenario with 40% glazing using standard double glazing in climate zone 4, there may be no premium or a very small premium. For the same amount and type of glazing in climate zone 8, the proposed scenario is compared with a baseline of 20% WWR, and the additional glazing area would come at a cost. However, this cost would be offset by a decrease in required wall area compared with the baseline, and the overall incremental capital cost of the scenario would depend on the cost of the specified wall performance compared with the baseline, as well as the window performance and area.

Air tightness

Infiltration	Description	Cost
0.2	Code	30,000
0.1	Half of code; add an interim test + trades training.	55,000
0.01	Passive house (approximately); add extra interim test.	75,000

	Source: local airtightness testing firm, local envelope consultant, checked against 2018 report.	
Lighting savings	No cost premium included for lower lighting power density. All baselines represent LED and include occupancy sensor and daylighting control where required. There continue to be improvements in LED technology to reduce LPDs.	
HVAC System Type	No cost premium included for HVAC system type, because the switch between, for example, baseboard to fan coil in MURBs is not an ECM, rather it is a program variation. It is not driven by energy, but by space or maintenance requirements, addition of cooling, or owner requirements.	
Heating	Standard Boiler: 25% savings vs condensing. $64/kW equivalent capacity Condensing Boiler: $25/MBH. $85/kW equivalent capacity ASHP: 2-pipe, $2750/ton. $357/kW equivalent capacity Capacity based on per floor area rule of thumb rather than model to be conservative and allow for adequate safety factor etc., using 50 btu/hr/sf. Actual savings likely available for higher performing envelope scenarios. Source: local contractor (for system fully installed), checked against RSMeans.	
HRV	Residential (individual unit per suite) None: $0/suite 60-65%: $1600/suite 80%: $4300/suite If the NECB 2015 baseline includes HRVs, there is a cost savings calculated if the proposed scenario has no HRVs, and a smaller cost premium for high-efficiency HRVs. Source: local contractor, HRV supplier, RSMeans	Commercial (large central unit(s)) None: $0/cfm 50-60%: $12/cfm 80%-90%: $24/cfm If the NECB 2015 baseline includes HRVs, there is a cost savings calculated if the proposed scenario has no HRVs, and a smaller cost premium for high-efficiency HRVs. Source: local contractor, RSMeans
Drain-water Recovery	20%: low flow fixtures, no cost premium 40%: low flow fixtures + drainwater heat recovery, $3.71 /$m^2$ of floor area Source: 2018 Metrics Report, plus inflation	

Table B2. Passive Cooling Measures

Passive Cooling Measure	Cost
Night Pre-cool	No cost, controls measure
HRV Bypass	Allowed for double the unit equipment cost, at same labour rate, based on RSMeans data, at $0.7/cfm. Added 0.1$m^2$ (1ft^2) of extra floor area per suite (3201$/$m^2$ ($297.5/sf) base construction cost, average 10 suites/floor). Total additional equipment cost 0$.51/ m^2, additional space allowance $4.6/ m^2.
HRV Boost	20% boost. Allowed for 20% additional cost including labour based on smallest HRV units in RSMeans, plus one extra ft2 per unit as was done

	with HRV bypass. Bypass equipment premium allowance $0.31/m^2, bypass extra space allowance $4.6/m^2.
Overhang	$ 2657 / linear meter ($810.15 / linear foot) per RSMeans Length uses 70% of perimeter of building (some length anticipated to not have window). Reduced by half if WWR is 20%. Total premium $291/m^2 of building area, $146/m^2 for 20% WWR case.
Fin	Uses same per linear meter cost as overhang. Fin length uses 1.5m length from top to bottom of fin, and average of 6 fins per façade = 24 fins/building Total premium $149/ m^2 of building area, $74/ m^2 for 20% WWR case.
Exterior Shade	Several sources and options considered and average of values was used (many options for manual vs controlled, different mounting options, etc.) Insulative shade (RSMeans): $229.73/ m^2 Interior insulated shutter (RSMeans): $80.05/ m^2 Consumer roller shade, exterior motorized, equipment only but without any bulk purchase deal: $107.6/ m^2 Using $139/ m^2 of window area Total premium $17 - 50/ m^2 of building area (varies based on WWR)

Table B3. Building Base Costs

Altus Construction Guide provides a range of costs for each building type. The mid-point of the range is used.

MURB	Vancouver - mid point for 7-39 storeys	3201 $/m^2 (297.5 $/ft^2)
Office	Vancouver - mid point for 5 - 30 storeys, average of Class A and B	3120 $/m^2 (290 $/ft^2)
Retail	Big box – Vancouver mid-point Mall - Vancouver mid-point	2260 $/m^2 (210 $/ft^2) 3416 $/m^2 (317.5 $/ft^2)
Hotel	Vancouver - mid from Budget to 4 Star	3282 $/m^2 (305 $/ft^2)

Appendix C: Detailed Modelling Output Tables

*Note that Part 9 results tables have incorrectly formatted percentages – where % better than ERS or % better than envelope read in the thousands, this should be divided by 100 to view the actual percentage (e.g. 5000% should be read as 50%). This was due to an error in converting from program outputs to excel formatted values for final presentation only and does not impact outcomes.
