1. Project Overview

1.1 Area of Interest

Eagle Mapping Ltd. collected aerial LiDAR over the Nanaimo, BC in a single lift occurring on February 9, 2016. The three Areas of Interest (AOIs) for this project cover a total of 186 sq km. LiDAR acquisition included the City of Nanaimo plus additional regions extending into neighbouring lands under the jurisdiction of the Regional District of Nanaimo. All areas were collected with a minimum 100m buffer to ensure adequate coverage for classification.

1.2 File Formats, Units, and Projection

Project deliverables include the following:

LAS Data

- Calibrated, raw unclassified LiDAR files in LAS format (v 1.4)
- Contains 16-bit intensity values, OGC WKT projection, return count, etc.
- Delivered as one file per laser channel per flight line

LiDAR Waveform

- Waveform data packets matching each flight line in .wdp format
- To be delivered at a future date

Flight Line Trajectories

- 200Hz position and attitude information in ASCII format
- Delivered as one file per laser channel per flight line

Survey Control Points

- Comprehensive ground survey delivered in Excel .xlsx and .txt formats

LiDAR Data Report

- Overview of project specifications, methodology and accuracies achieved
- PDF format

Map Projection Information	
Projection	UTM zone 10N
Horizontal Datum	NAD83 (CSRS)
Vertical Datum	CGVD28
Geoid	HTv2.0
Units	Meters
EPSG Code	3157

2. Acquisition & Calibration

2.1 Airborne LiDAR Collection

A Riegl Q1560 dual-channel LiDAR system was used for acquisition of the LiDAR data. This system was installed in Eagle Mapping's Cessna 206 aircraft, which is based in Pitt Meadows, BC. In total, 28 flight lines were required to cover the AOI. Nominal flying height was 1250m above ground level (AGL) over the city, and 1700m over the watershed. The lower altitude over the city was to provide higher point density over this area. Flight speed was approximately 115kts. The scan field of view for the Riegl Q1560 is 29° either side of nadir, for a total scan field of view of 58°. The scan rate used for this project was 800 kHz. However, due to the nature of the 4-sided rotating mirror in Riegl scanners only 2/3 of pulses are recorded (533 kHz useable). This yields an average pulse density of 3 pulses per channel per swath (6 pulses per dual-channel flight line) for the city acquisition, and 2 pulses per channel – 4 per flight line over the watershed area. Note, each pulse may result in one or more returned points as the pulse filters through vegetation, etc. All areas were captured with at least 60% side overlap, so expected pulse density would be twice the per-line densities listed above.

Along the coastline and tidal areas, LiDAR was collected within an hour on either side of the daily low tide posted by Fisheries and Oceans Canada.

LiDAR Acquisition Specifications	
Flight Altitude	1250m & 1700m AGL
Flying Speed	115kts nominal
Scan Rate	800khz (533khz usable)
Scan Field of View	58°
Line Spacing	550m & 750m
Minimum Overlap	60% (double coverage + 10%)

2016-02-09 (Tuesday)		
Time	Height	
	PST	(m)
06:37	4.7	15.4
12:21	2.7	8.9
17:36	4.3	14.1

2.2 Aircraft GNSS Trajectory Processing

GNSS post-processing determines the position and attitude of the aircraft at a rate of 200 observations/second along the entire flight path. This data is logged on the Q1560 via an Applanix POS AV510. Post-processing requires data from the onboard GNSS and Inertial Measurement Unit (IMU) as well as data from one or more static GNSS base station(s) with known coordinates.

Processing is performed with Applanix PosPAC v7.1 software. Here the aircraft GNSS / IMU data is referenced to the base station data to provide adjusted positions for the aircraft in latitude, longitude, and height, roll, pitch, and yaw / heading. The final trajectory is then smoothed, and exported in .pos format for use in RiProcess for LiDAR processing. The resulting flight path is commonly referred to as a Smoothed Best Estimate of Trajectory (SBET).

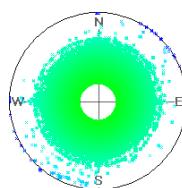

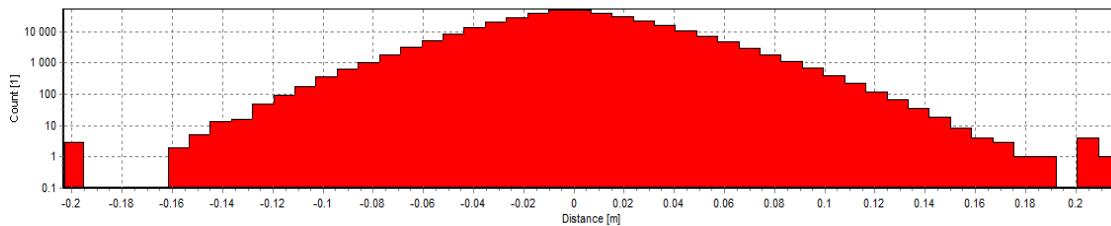

Mission planning ensures the project is flown during a period of good satellite visibility, resulting here in an average PDOP of 1.5 and maximum of 2.0. Statistical accuracy (RMS) of the SBET trajectory is < 2cm.

The base station used for this project is a continually-operating station operated which is part the Can-Net reference station network. This particular station (Station ID - NANA) is located outside the Nanaimo City Hall building.

Trajectory Processing Results	
Min. # of Satellites	11
Max. # of Satellites	17
Minimum PDOP	1.2
Maximum PDOP	2.2
RMSE	1.9 cm

2.3 LiDAR Calibration

LiDAR data was calibrated using Riegl RiProcess software. A quality check was performed using matching tie planes which are calculated automatically and analyzed via a least-squares adjustment. Manual cross section checks were also performed to verify the automatic results. Internal accuracy of the LiDAR data was calculated at ± 0.029 . Once deemed properly calibrated, the LAS data is exported along with individual 'trajectories' for each scan line. All data is projected into UTM and adjusted to the proper vertical datum (CGVD28) at this time.

3. Ground Control Measurement

Our survey technicians use dual-frequency Trimble R6 and R8 GNSS receivers to measure ground control points. These receivers are capable of establishing and measuring points to a high degree of accuracy (usually in the 1-2cm range). Survey processing is done with Trimble Business Center software.

For this project, 193 points were measured throughout the 3 project areas (57 at Jump Lake and 136 in the City of Nanaimo). Most points are located in open terrain where it is likely to receive a LiDAR return. Several others were measured under tree cover in order to verify LiDAR accuracy in vegetation. Generally, the control points are used for vertical accuracy verification only, but when possible, features are surveyed for horizontal assessment as well. Horizontal check points would include large paint lines, pavement edges, grass / gravel interface, etc and in some cases were features not suitable for vertical accuracy assessment (ie. bridge deck). These points as well as several significant outliers were removed from vertical accuracy reporting.

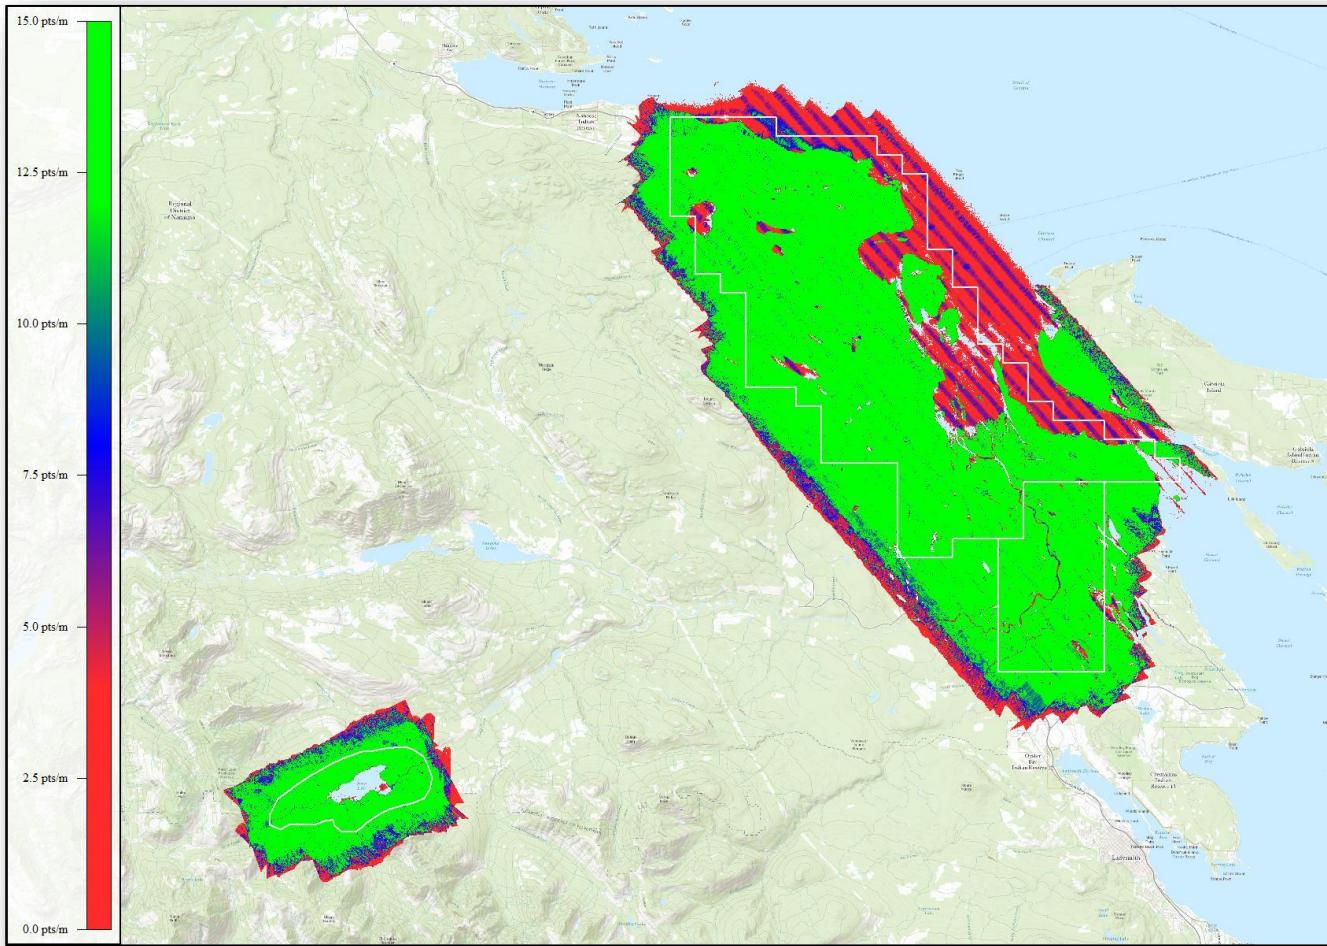

4. Results and Conclusions

4.1 Point Density and Coverage

LiDAR data was collected over the city with an average density of 15-20 points / sq. meter for all returns, and 12-14 points / sq. meter counting only first-returns. Over the Jump Lake watershed the average density is 12-15 points for all returns and 8-10 counting only first returns. Density is much greater for all returns vs first-returns due to the full waveform analysis performed by the Q1560 laser. By analyzing the full LiDAR waveform, the Q1560 is able to extract many additional points in vegetation, or other terrain where the laser pulse is 'filtered' through many objects in close proximity to each other.

A coverage / density plot is shown below. Water bodies will indicate a very low return density which is due to the absorption on the laser pulse by water.

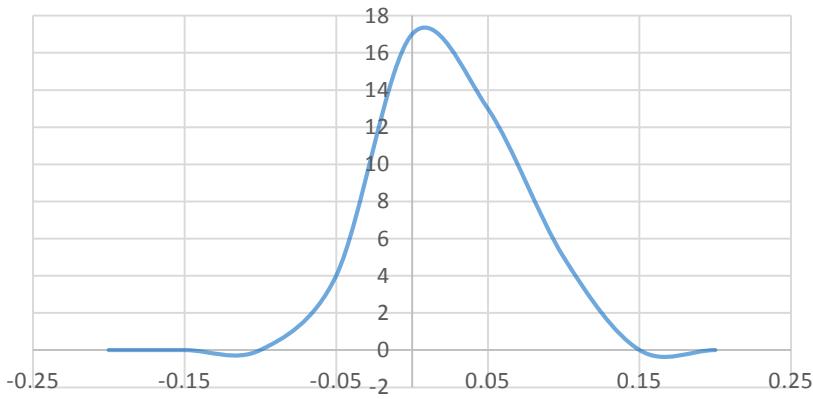

4.2 Accuracy

LiDAR Accuracy

Accuracy of the LiDAR data was determined via comparison to a set of ground control points measured by an Eagle Mapping surveyor. LiDAR data was measured to fit these control points very well but a slight vertical bias was observed. The Jump Lake LiDAR data was adjusted by -7.5cm in order to best fit the control points.

This dataset was tested to meet ASPRS Positional Accuracy Standards for Digital Geospatial Data (2014) for a <10.0cm RMSE_z Vertical Accuracy Class. Actual Non-Vegetated Accuracy (NVA) was found to be RMSE_z = 4.0cm, equating to ± 7.8 cm at 95% confidence level. Vegetated Vertical Accuracy (VVA) was found to be ± 14.5 cm at the 95th percentile. Relative accuracy was observed to meet USGS Quality Level 1 standards: Smooth Surface Repeatability <6cm, Swath Overlap Difference RMSD_z <8cm, and Swath Overlap Difference Maximum <16cm.

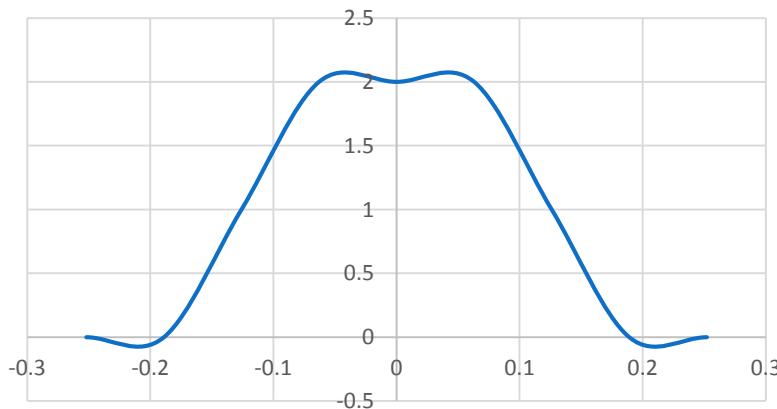

Non-Vegetated Accuracy Plot

LiDAR Accuracy (NVA)

Average dZ	+0.001
Minimum dZ	-0.074
Maximum dZ	+0.092
